Executive summary

Alcohol consumption has been identified as a major risk factor for mortality and burden of disease. Switzerland has a consumption level which is more than 50% above the global average, and consequently it incurs a comparatively high level of mortality. In 2011, the most recent year with data on exposure, we estimate 2'683 deaths due to alcohol. In the age group of 15-74 years of age, where more reliable data on cause of deaths are available compared to the age group 75 and older, 1'600 people died due to alcohol, 1'181 men and 419 women. This corresponds to 1 out of 10 premature deaths in adult men and more than 1 out of 17 in adult women caused by alcohol. These numbers are net numbers, already taking into account the protective effects of light to moderate consumption on ischaemic disease and diabetes. Three main broad causes of death are mainly contributing to this mortality toll, cancers, injury and digestive disease. Although alcohol causes considerable cardiovascular deaths, these deaths are cancelled out by the above described protective effects on ischaemic diseases, mainly ischaemic heart disease. The causes of death underlying alcohol-attributable deaths change over the life course. In young adulthood, they are mainly due to injury, in middle adulthood, digestive diseases become more prevalent, and for last decades up to 74 years of age, cancers are the leading cause of alcohol-attributable death. Overall, the relative proportion of alcohol-attributable mortality to all mortality is highest in young adulthood, but the absolute numbers of alcohol-attributable diseases increase with age. As a consequence, alcohol-attributable years of life lost (YLL) make up even a larger proportion of all years of life lost than alcohol-attributable deaths of all deaths. Overall, 42'627 years (men: 30'880; women: 11'747) of life are lost by premature death among the 15-74 year olds.

Overall, 62% of the net deaths were attributable to heavy drinking as defined by 40 g/day or more of pure alcohol for women and 60 g/day or more for men. The proportion was larger (67%) for men than for women (48%). In other words, the majority of alcohol-attributable deaths among 15-74 year olds in Switzerland had been caused by heavy drinking. There are no protective effects of heavy drinking.

The level of alcohol consumption has gone down since 1997, the starting date for our investigation. As binge drinking (5 or more standard drinks for men and 4 or more standard drinks for women) did not seem to increase, it is no surprise that the rates of alcohol-attributable deaths have gone down as well. However, this effect is restricted to men, and for women we do not see any decrease in alcohol-attributable mortality. The death rate per 100'000 resident women remained stable only because the residential population increased. Over the time period observed in this study, there is a more than 20% increase in the absolute number of alcohol-attributable deaths among women (1997: 340; 2011: 419), and also the proportion of alcohol-attributable death on all deaths increased from 4.3% to 6.0%.

The results have some implications. Policies should be implemented to further support the overall positive trend of decreasing alcohol-attributable mortality burden. A particular focus should be given to women. As a large share of alcohol-attributable mortality is due to heavy drinking, policies but also preventive actions should not only be universal but also selective targeting heavy drinkers including sufficient provision of treatment options.

Zusammenfassung

Alkoholkonsum ist ein bedeutsamer Risikofaktor bezüglich Mortalität und Krankheitslast. Die Schweiz hat einen Alkoholkonsum, der mehr als 50% über dem globalen Durchschnitt liegt, entsprechend fällt die alkoholbedingte Mortalität vergleichsweise hoch aus. Für das Jahr 2011 – das letzte Jahr mit verfügbaren Konsumdaten – schätzen wir 2'683 alkoholbedingte Todesfälle. Betrachten wir nur die Altersgruppe der 15 bis 74-Jährigen, in der im Vergleich zu den über 74-Jährigen zuverlässigere Angaben zu den Todesursachen vorliegen, beträgt die geschätzte Anzahl der alkoholbedingten Todesfälle 1'600, wovon 1'181 Männer und 419 Frauen betreffen. Das entspricht 1 von 10 vorzeitigen Todesfällen bei Männern und 1 von 17 bei Frauen, die durch Alkohol bedingt sind. Diese Zahlen berücksichtigen bereits die protektiven Effekte von Alkohol auf ischämische Krankheiten und Diabetes, es handelt sich also um Netto-Zahlen. Krebse, Unfälle und Verletzungen sowie Krankheiten des Verdauungssystems machen den Grossteil der alkoholbedingten Todesfälle aus. Alkohol verursacht zwar auch eine beträchtliche Anzahl von Herztdoden, diese werden aber durch die bereits erwähnten protektiven Effekte auf ischämische Krankheiten, primär ischämische Herzkrankheiten, wieder ausgeglichen. Die Art der alkoholbedingten Todesursachen verändert sich mit dem Verlauf des Alters. Bei jungen Erwachsenen sind es primär Unfälle und Verletzungen, während im mittleren Erwachsenenalter vermehrt Krankheiten des Verdauungssystems auftreten und im höheren Alter bis 74 Jahre mehrheitlich Krebse. Der relative Anteil der alkoholbedingten Todesfälle an allen Todesfällen ist am grössten bei den jungen Erwachsenen, hingegen steigt die absolute Anzahl der alkoholbedingten Todesfälle mit dem Alter an. Folglich ist der Anteil der alkoholbedingt verlorenen Lebensjahre an allen verlorenen Lebensjahren noch höher als der Anteil der alkoholbedingten Tode. Insgesamt gehen 42'627 Lebensjahre (Männer: 30'880, Frauen 11'747) aufgrund von vorzeitigen Todesfällen bis zum Alter von 74 Jahren durch Alkohol verloren.

Insgesamt waren 62% der alkoholbedingten Netto-Tode auf starken Alkoholkonsum zurückzuführen. Starker Alkoholkonsum wurde definiert als mehr als 40 Gramm pro Tag bei Frauen und mehr als 60 Gramm pro Tag bei Männern. Anders ausgedrückt geht die Mehrheit der alkoholbedingten Tode in der Schweiz auf chronisch starken Alkoholkonsum zurück. Es gibt keine protektiven Effekte bei chronisch starkem Alkoholkonsum.

Seit 1997, dem ersten berücksichtigten Jahr in dieser Studie, ist der Pro-Kopf-Alkoholkonsum stetig zurückgegangen. Da es auch keine Anzeichen für eine Zunahme im Rauschtrinken gab, ist es nicht überraschend, dass die alkoholbedingten Todesfälle auch rückläufig sind. Dieser Trend ist allerdings auf Männer beschränkt, bei Frauen ist kein Rückgang der alkoholbedingten Todesfälle feststellbar. Die Todesraten per 100'000 Einwohnerinnen bleiben stabil, da auch die Population angestiegen ist. Die absolute Zahl der alkoholbedingten Todesfälle bei Frauen stieg um über 20% (1997: 340; 2011: 419) an, und auch der Anteil der alkoholbedingten Todesfälle an allen Todesfällen stieg von 4.3% auf 6.0%.

Aus diesen Resultaten lassen sich einige Schlussfolgerungen ableiten. Es sollten Massnahmen implementiert werden, um den insgesamt positiven Trend zurückgehender alkoholbedingter Todesopfer weiter zu unterstützen. Dem Alkoholkonsum von Frauen sollte dabei spezielle Aufmerksamkeit zukommen. Da ein grosser Teil der alkoholbedingten Todesfälle auf chronisch starken Konsum zurückzuführen ist, sollten präventive Massnahmen nicht nur universell die Allgemeinheit betreffen, sondern sich auch selektiv an stark Alkoholkonsumierende richten. Dies schliesst insbesondere die ausreichende Bereitstellung von indizierten Behandlungsmöglichkeiten ein.

Résumé

La consommation d'alcool constitue un facteur de risque majeur de mortalité et de fardeau des maladies. Le niveau de consommation en Suisse est de plus de 50% au dessus de la moyenne mondiale, ce qui par conséquent implique un niveau élevé de mortalité. En 2011, année la plus récente avec des données sur l'exposition, nous estimons à 2'863 le nombre de décès dus à l'alcool. Parmi les personnes de 15 à 74 ans, pour lesquelles des données plus fiables sont disponibles que pour celles de 75 ans et plus, 1'600 sont mortes à cause de l'alcool (1'181 hommes et 419 femmes). Cela correspond à 1 décès prématué sur 10 pour les hommes et 1 sur 17 pour les femmes. Il s'agit de chiffres nets, qui tiennent compte de l'effet protecteur d'une consommation légère à modérée sur les maladies ischémiques et le diabète. Trois causes de décès en général ont principalement contribué à ce bilan de mortalité : les cancers, les blessures et les maladies digestives. Bien que l'alcool provoque un nombre considérables de décès liés aux maladies cardiovasculaires, ce nombre est contrebalancé par les effets protecteurs sur les maladies ischémiques décrites ci-dessus, et particulièrement les maladies ischémiques cardiaques. Les causes sous-jacentes des décès attribuables à l'alcool changent au cours de la vie: chez les jeunes adultes, les décès sont principalement dus à des blessures, au milieu de l'âge adulte, les maladies digestives deviennent plus répandues, et, pour les plus âgés jusqu'à 74 ans, les cancers sont la première cause de décès attribuables à l'alcool. D'une manière générale, la proportion relative de mortalité attribuable à l'alcool parmi toutes les causes de mortalité est la plus élevée chez les jeunes adultes, mais le nombre absolu de maladies attribuables à l'alcool augmente avec l'âge. En conséquence, la part des années de vie perdues à cause de l'alcool parmi toutes les années de vie perdues est nettement plus importante que celle des décès liés à l'alcool. Au total, 42'627 années de vie (30'880 pour les hommes et 11'747 pour les femmes) sont perdues pour cause de décès prématué, parmi les personnes de 74 ans ou moins.

D'une manière générale, 62% du nombre net de décès est attribuable à la consommation chronique élevée d'alcool, définie comme la consommation de 40g/jour ou plus d'alcool pur pour les femmes et 60g/jour ou plus pour les hommes. Cette proportion était plus élevée parmi les hommes (67%) que les femmes (48%). En d'autres termes, la majorité des décès attribuables à l'alcool parmi les personnes de 15 à 74 en Suisse ont été causés par la consommation chronique élevée d'alcool. Il n'y a pas d'effet protecteur de la consommation chronique élevée d'alcool.

Le niveau de consommation d'alcool a diminué depuis 1997, année de départ de notre étude. Comme la consommation épisodique à risque (aussi appelée binge drinking), définie comme la consommation de 5 verres standard ou plus pour les hommes et 4 ou plus pour les femmes, ne semble pas en augmentation, il n'est pas surprenant que le taux de décès attribuable à l'alcool ait aussi baissé. Toutefois, cette diminution n'est observable que pour les hommes. Le taux de mortalité pour 100'000 femmes résidentes n'est resté stable que parce que la population résidente dans son ensemble a augmenté. Sur l'ensemble de la période étudiée, il y a une augmentation de plus de 20% du nombre absolu de décès attribuables à l'alcool chez les femmes (1997: 340, 2011: 419) et la proportion de décès attribuable à l'alcool sur l'ensemble des causes de décès a également augmenté, passant de 4.3% à 6.0%.

Ces résultats ont des implications. Il faudrait mettre en œuvre des mesures visant à soutenir la tendance générale positive allant vers une diminution du fardeau de la mortalité attribuable à l'alcool. Une attention particulière devrait être accordée aux femmes. De plus, comme une part importante de la mortalité attribuable à l'alcool est due à la consommation chronique élevée, les mesures et actions de prévention ne devraient pas uniquement s'adresser à l'ensemble de la population, mais aussi sélectivement aux consommateurs excessifs, et notamment la mise à disposition de suffisamment d'options de traitement.

1 Monitoring of alcohol-attributable mortality

In 2010, the World Health Assembly endorsed a Global Strategy to reduce the harmful use of alcohol (World Health Organization, 2010). Part of this strategy was the call to all member states to establish monitoring systems for alcohol consumption and alcohol-attributable harm. Such monitoring systems enable countries not only to assess and quantify alcohol-attributable health burden, but also to track such burden over time, quickly identify problematic developments and plan appropriate action (Rehm and Scafato, 2011, Rehm and Room, 2009). Mortality is the most severe consequence linked to alcohol, and has been identified to be the key part of any such monitoring system (Rehm and Scafato, 2011). To track alcohol-attributable mortality in a country, basically three elements are necessary:

- Information about alcohol exposure for the dimensions relevant for the outcome;
- Information about risk relations (i.e., which level of alcohol exposure is linked to which risk in comparison to no alcohol consumption)
- Information about the outcomes, i.e. distribution of causes of death.

For Switzerland, all these information are present given the good data infrastructure with respect to

- ⇒ routine data collection to estimate *per capita* alcohol consumption by the Eidgenössische Alkoholverwaltung (Swiss Alcohol Board, latest overview: (Eidgenössische Alkoholverwaltung, 2012)), which is a federal agency and part of the Swiss Federal Department of Finance;
- ⇒ regular surveys which include detailed assessment of relevant dimensions of consumption stemming from the Swiss Health Surveys (Delgrande and Notari, 2011);
http://www.bfs.admin.ch/bfs/portal/de/index/infothek/erhebungen_quellen/blank/blank/ess/04.html and, more recently from the Addiction Monitoring System in Switzerland (Gmel et al., 2012); and
- ⇒ a vital registration system providing yearly data on causes of death as published by Swiss Statistics (http://www.bfs.admin.ch/bfs/portal/en/index/infothek/erhebungen_quellen/blank/blank/cod/02.html).

Thus, Switzerland has all the necessary elements to start a monitoring system on alcohol-attributable mortality as outlined by the World Health Organization. This report will provide a first base by estimating alcohol-attributable mortality for the years 1997 to 2011 in a comparative fashion, as well as providing a complete overview of the underlying methodology. The authors hope that it becomes the nucleus of a wider routine alcohol monitoring system, as alcohol continues to be one of the major risk factors for burden of disease not only in Switzerland and Europe, but also globally (for the latest publications regarding Switzerland and Europe see (Shield et al., 2012b, Rehm et al., 2012); for global estimates (Rehm et al., 2009a, World Health Organization, 2009, World Health Organization, 2011, Lim et al., 2012), but the latter GBD 2010 estimates will be corrected).

2 Methodology

2.1 Data sources

Alcohol exposure data

Alcohol exposure data were taken from the three Swiss Health Surveys conducted in 1997, 2002, and 2007, and the Continuous Rolling Survey of Addictive Behaviours and related Risks (CoRoLAR) within the Addiction Monitoring System in Switzerland (AMIS; (Gmel et al., 2012); see above). These surveys provide prevalence for abstainers and former drinkers; and average alcohol use in grams per day for different age groups by sex. They also provide data for binge drinking (i.e. drinking a large amount on single occasions). Over the years different definitions of binge drinking were used. For bingeing prevalence (5+ drinks on one occasion for men and 4+ drinks on one occasion for women) and bingeing frequency (i.e., binge occasions per year among drinkers) AMIS 2011 and SHS 2007 data were used. Because SHS 1997 and 2002 had no estimates for 5+/4+ drinks on one occasion, we used the SHS 2007 estimates among drinkers to derive estimates for the SHS 2002 and SHS 1997 as earlier work on bingeing prevalence showed remarkable temporal stability (Wicki and Gmel, 2005); see also

<http://www.bag.admin.ch/themen/drogen/00039/00600/04639/index.html?lang=de.>

Survey estimates were triangulated with *per capita* consumption data as described in detail below. Recorded *per capita* consumption estimates were taken from the Eidgenössische Alkoholverwaltung (Swiss Alcohol Board, latest overview: (Eidgenössische Alkoholverwaltung, 2012)). Adult *per capita* consumption estimates were recalculated for the 15+ years population, assuming that people below 15 do not contribute markedly to the *per capita* consumption. Unrecorded estimates were taken from the World Health Organization Global Information System on Alcohol and Health (GISAH: <http://apps.who.int/ghodata/?theme=GISAH> ; see also (World Health Organization, 2011), for the most recent estimate). Unrecorded consumption in Switzerland is relatively low, with less than 5% of the overall consumption being estimated to be unrecorded. For estimating uncertainty of *per capita* consumption, we used the method developed for CRA, which is based on estimates for *per capita* consumption from different sources (FAO, countries, industry – for general sources of *per capita* information see (Rehm et al., 2007, Rehm et al., 2003a); for combining the various sources of uncertainty into an uncertainty interval for attributable fractions see below).

Selection of alcohol-attributable disease categories

The broad categories of disease attributable to alcohol were taken from the Comparative Risk Assessment (CRA) for alcohol as part of the Global Burden of Disease and Injury (GBD) 2010 study (for a general introduction into GBD categories see (Murray et al., 2012); for the CRA see (Lim et al., 2012); for categories specifically related to alcohol see (Rehm et al., 2010a)). As Switzerland has a vital registration system with detailed causes of death, we were able to include some finer categories as the GBD (as detailed in Table 1.) This was especially true for the 100% attributable causes of death, i.e., the disease and injury categories, which would be completely missing in the absence of alcohol in a society (shaded in gray in Table 1).

Table 1 outlines the alcohol-attributable causes of death by International Classification of Disease (ICD) (revision 10) code (World Health Organization, 2007) as obtained from the overview publication of Rehm and colleagues (Rehm et al., 2010a).

Table 1: Disease and injury categories causally impacted by alcohol

Category	ICD-10 code
Infectious and parasitic diseases	
Tuberculosis	A15-A19, B90
HIV/AIDS	B20-B24
Malignant neoplasms	
Mouth, nasopharynx, other pharynx and oropharynx cancer	C00-C14
Oesophagus cancer	C15
Colon and rectal cancer	
Colon cancer	C18
Rectal cancer	C19-C21
Liver cancer	C22
Larynx cancer	C32
Breast cancer (female)	C50
Diabetes mellitus	E11-E14
Alcohol-induced pseudo-Cushing's syndrome	E24.4
Neuropsychiatric conditions	
Mental and behavioural disorders due to use of alcohol	F10
Acute intoxication	F10.0
Harmful use	F10.1
Dependence syndrome	F10.2
Withdrawal state	F10.3
Withdrawal state with delirium	F10.4
Psychotic disorder	F10.5
Amnesic syndrome	F10.6
Residual and late-onset psychotic disorder	F10.7
Other mental and behavioural disorders	F10.8
Unspecified mental and behavioural disorder	F10.9
Degeneration of nervous system due to alcohol	G31.2
Epilepsy	G40, G41
Alcoholic polyneuropathy	G62.1
Alcoholic myopathy	G72.1
Cardiovascular diseases	
Hypertensive heart disease	I11-I13
Ischaemic heart disease	I20-I25
Cardiomyopathy	
Alcoholic cardiomyopathy	I42.6
Conduction disorders and other dysrhythmias	I47-I49
Cerebrovascular disease	
Hemorrhagic and other non-ischaemic stroke	I60-I62, I69.0, I69.1, I69.2
Ischaemic stroke	I63-I67, I69.3
Digestive diseases	
Alcoholic gastritis	K29.2
Cirrhosis of the liver (we restricted ourselves to Alcoholic liver disease)	K70, K73-K74
Alcoholic liver disease	K70
Alcoholic fatty liver	K70.0
Alcoholic hepatitis	K70.1
Alcoholic fibrosis and sclerosis of liver	K70.2
Alcoholic cirrhosis of liver	K70.3
Alcoholic hepatic failure	K70.4
Alcoholic liver disease, unspecified	K70.9
Pancreatitis (we used AAF for the larger category based on RR)	K85, K86.0, 86.1
Alcohol-induced acute pancreatitis	K85.2
Alcohol-induced chronic pancreatitis	K86.0

Category	ICD-10 code
Respiratory infections	
Lower respiratory infections: pneumonia	J09–J22, J85
Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified	
Finding of alcohol in blood	R78.0
Injury, poisoning and certain other consequences of external causes	
Toxic effect of alcohol	T51
Ethanol	T51.0
Methanol	T51.1

Remark: Grey-shaded categories are 100% attributable to alcohol.

Risk relation data

Risk relation specifications were also taken from the CRA for alcohol within the GBD 2010 study. By definition, all causes of death with “alcohol”, “alcoholic” or “alcohol-induced” in their name are 100% attributable to alcohol, and need no specification for risk relations (see grey shaded cells in Table 1). For all others factors, risk relations were derived from meta-analyses (in order of appearance in Table 1);

- Tuberculosis (Lönnroth et al., 2008);
- HIV/AIDS (specifically only for the impact of alcohol on mortality via its impact on medication see (Gmel et al., 2011a); see also (Rehm et al., 2009b))
- Malignant neoplasms (of course specific risk relations for each category: (Corrao et al., 2004))
- Diabetes mellitus (Baliunas et al., 2009)
- Epilepsy (Samokhvalov et al., 2010a)
- Hypertension and hypertensive heart disease (Taylor et al., 2009)

- Ischaemic heart disease (Roerecke and Rehm, 2010, Roerecke and Rehm, 2012b)
- Conduction disorders and other dysrhythmias (Samokhvalov et al., 2010b)
- Stroke (Patra et al., 2010)
- Pancreatitis (Irving et al., 2009)
- Pneumonia (Samokhvalov et al., 2010c)
- Injury (Taylor et al., 2010)

Outcomes (cause of death and years of life lost) data

The comprehensive and completely anonymized death statistic was obtained from the Swiss Federal Statistical Office for all years since 1997

(http://www.bfs.admin.ch/bfs/portal/en/index/infothek/erhebungen_quellen/blank/blank/cod/02.html), including ICD-10 code of cause of death, sex, and age at death to calculate years of life lost. Years of life lost used life tables from the Swiss Federal Office of Statistics (<http://www.bfs.admin.ch/bfs/portal/de/index/themen/01/06/blank/key/04/04.html>), detailing life expectancies at age of death. No discounting was applied. The latest available death statistic obtainable from the Swiss Federal Statistical Office was for 2010, which was used as the best proxy for 2011, the year for which alcohol use data were available.

Population data

Distribution of population aged 15 years and above across age and strata was used to triangulate survey data with adult per capita consumption data. The population distribution was obtained from the Swiss Federal Statistical Office (<http://www.pxweb.bfs.admin.ch>).

2.2 Modelling the distribution of alcohol consumption

The distribution of average daily alcohol consumption was modelled using the methods of the CRA for alcohol (Lim et al., 2012), as detailed in publications of the CAMH group (Rehm et al., 2010b, Kehoe et al., 2012). There are two reasons for modelling alcohol consumption using drinking status prevalence survey estimates and *per capita* consumption (PCC) data (Rehm et al., 2007): 1) it enables comparisons of alcohol consumption and alcohol-related harms between different countries and populations (Rehm et al., 2004, Lachenmeier et al., 2009), and 2) triangulation corrects for the underestimation of alcohol consumption which is observed when comparing survey data to per capita consumption, which if left uncorrected results in an underestimation of the burden of disease attributable to alcohol.

For the purposes of modelling alcohol consumption, the total alcohol consumed by the population was set to 80% of total adult *per capita* alcohol consumption in order to account for alcohol produced and/or sold, but not consumed (Gmel and Rehm, 2004, Shield and Rehm, 2012) and to account for underestimation of alcohol consumption in observational alcohol epidemiology studies (Rehm et al., 2010a); these studies provide the underlying risk relations for the meta-analyses used in calculating the alcohol-attributable burden of disease (see above).

Basically, survey results are upshifted or downshifted to amount to 80% of adult *per capita* consumption; for Switzerland, all survey estimates were considerably lower than the *per capita* data, so they had to be upshifted. This upshifting is possible, as the population distribution of alcohol can be approximated well by a

two parameter gamma distribution, which is defined by a shape and a scale parameter, which in turn can be derived from its mean and standard deviation (Kehoe et al., 2012). The mean is obtained from a combination of adult *per capita* and survey data. The survey data is used to split the *per capita* into sex and age specific mean alcohol consumption values that can be used to derive the gamma distribution parameters. Analyzing a large number of alcohol surveys, Rehm and colleagues observed that the standard deviation (σ) of the alcohol consumption distribution of a given population can be predicted by sex from the mean (μ) as follows (Rehm et al., 2010b, Kehoe et al., 2012):

$$\sigma_{men} = 1.171 * \mu_{men}$$

$$\sigma_{women} = 1.258 * \mu_{women}$$

2.3 Calculating the number of alcohol-attributable deaths

The number of deaths for disease and injury categories that are not entirely attributable to alcohol consumption was calculated using the alcohol-attributable fraction methodology (Walter, 1976, Walter, 1980, Benichou, 2001). The alcohol-attributable fraction (AAF) is defined as the proportion of deaths that would not have occurred for a given time period if everyone were a lifetime abstainer. Details of this methodology are outlined below separate for different disease categories.

Diseases partly attributable to alcohol consumption (except ischaemic heart disease and HIV/AIDS)

Deaths from diseases and conditions that are in part attributable to alcohol consumption (except for ischaemic heart disease and HIV/AIDS) were calculated according to the average alcohol consumption risk model, where the risk of a disease or condition is estimated based on distribution of alcohol consumption, prevalence of current drinkers, former drinkers and lifetime abstainers, and the Relative Risk distribution (RR). The formula for these AAFs is given below:

$$AAF = \frac{P_{abs} + P_{former}RR_{former} + \int_{0+}^{150} P_{current}(x)RR_{current}(x)dx - 1}{P_{abs} + P_{former}RR_{former} + \int_{0+}^{150} P_{current}(x)RR_{current}(x)dx}$$

where P_{abs} represents lifetime abstainers, P_{former} is the prevalence of former drinkers, RR_{former} is the RR for former drinkers, $P_{current}$ is the prevalence of current drinkers who consume an average daily amount (x) of alcohol, and $RR_{current}$ is the RR given an average daily consumption of x .

Ischaemic heart disease attributable to alcohol consumption

The number of deaths of ischaemic heart disease that were attributable to alcohol consumption was calculated according to the methodology outlined below. The risk of ischaemic heart disease is impacted by both the average volume of alcohol consumption and the patterns of drinking (in form of heavy drinking or binge occasions), and thus data on level of average alcohol consumption and on heavy drinking occasions were used for estimating the number of ischaemic heart disease deaths attributable to alcohol consumption (Puddey et al., 1999, Rehm et al., 2003b). For modelling the number of deaths from ischaemic heart disease that were attributable to alcohol consumption, we used the age dependent relative risk function that resembles a J-shaped curve ((Roerecke and Rehm, 2012b); see also (Corrao et al., 2000) or (Ronksley et

al., 2011) for similar results) for all individuals who did not engage in episodic or chronic heavy drinking. For people with at least one heavy drinking occasion (defined as drinking occasions where men consume 5 standard drinks or more (the equivalent of consuming 60 grams of alcohol during one drinking occasion) and where women consume 4 standard drinks or more (equivalent of consuming 48 grams of alcohol during one drinking occasion)) per month, we assumed there was no cardio-protective effect (Roerecke and Rehm, 2010).

HIV/AIDS deaths attributable to alcohol consumption

The number of HIV/AIDS deaths attributable to alcohol consumption was calculated using methodology outlined by Gmel and colleagues (Gmel et al., 2011a). This method calculates the number of such deaths as a result of non-adherence to medication due to alcohol consumption by combining data on the number of deaths in the population due to HIV/AIDS, the prevalence of people who require Highly Active Anti-Retroviral Treatment (HAART) and who are also receiving this treatment (obtained from the 2006 Report on the Global AIDS Epidemic (UNAIDS, 2006)), the rate of deaths among those individuals who receive HAART and those who do not (Murphy et al., 2001), the rate of deaths for those who adhere to HAART and for those who do not (Lima et al., 2008), and the hazard of not adhering to HAART if you are a current drinker as compared to a lifetime abstainer (Hendershot et al., 2009).

Injuries attributable to alcohol consumption

Mortality from injuries attributable to alcohol consumption was estimated according to methodology outlined by Shield and colleagues (Shield et al., 2012a). This estimation method uses data on alcohol consumption during both normal drinking days and heavy (binge) drinking days. For modelling the number of deaths due to injuries attributable to alcohol consumption, we used data on the prevalence of current drinkers, the prevalence of binge drinkers, per capita consumption of alcohol, the frequency of binge drinking, the amount of alcohol consumed during binge drinking occasions, and alcohol metabolism data (Taylor et al., 2011) (metabolism data were used to calculate the period of time during a drinking occasion when a person was at risk for an injury). The risk relationship between alcohol consumption and injuries was obtained from the meta-analysis performed by Taylor and colleagues (Taylor et al., 2010).

The AAFs for intentional and unintentional injuries attributable to alcohol consumption were calculated as follows:

$$AAF = \frac{P_{abs} + P_{form} + P_{current(non-binge)}RR_{current(non-binge)} + P_{current(binge)}RR_{current(binge)} - 1}{P_{abs} + P_{form} + P_{current(non-binge)}RR_{current(non-binge)} + P_{current(binge)}RR_{current(binge)}}$$

where P_{abs} represents the prevalence of lifetime abstainers, P_{form} is the prevalence of former drinkers, and $P_{current(binge)}$ and $P_{current(non-binge)}$ are the prevalence of current drinkers who engage in binge drinking and the prevalence of current drinkers who do not engage in binge drinking, respectively. $P_{current(binge)}$ and $P_{current(non-binge)}$ were calculated as follows:

$$P_{current(non-binge)} = P_{drinkers} * (1 - P_{bingers} * BingeTimes)$$

$$P_{current(binge)} = P_{drinkers} * (P_{bingers} * BingeTimes)$$

The RRs for current drinkers who engage in binge drinking and for current drinkers who do not engage in binge drinking (as a function of their average consumption) were calculated separately as follows:

$$RR_{current(non-binge)} = P_{dayatrisk}(average) * (RR_{injury}(average) - 1) + 1$$

and

$$RR_{current(binge)} = P_{dayatrisk}(BingeAmount) * (RR_{injury}(BingeAmount) - 1) + 1$$

In the above formulae, $P_{dayatrisk}$ represents the proportion of a day at risk, and $RR_{current(non-binge)}$ and $RR_{current(binge)}$ are the relative risks for injury given an average amount of alcohol consumed when not bingeing and the relative risk for injury when bingeing respectively. $P_{bingers}$ is the proportion of bingers among the drinking population and BingeTimes is the frequency (calculated as binge occasions per day) of bingeing among bingers. $P_{dayatrisk}$ is calculated based on the average rate at which alcohol is metabolized given the amount of alcohol used during a binge session (this was estimated as being 7 drinks on average for the male 5+ category and 6 drinks on average for the female 4+ category), thereby corresponding to the time during which the blood alcohol level is sufficiently elevated to increase the risk of injury.

The above-presented AAFs were determined based on RR estimates that were calculated using samples of emergency room patients and were calculated using alcohol RRs for morbidity from injury. To obtain the AAFs for injury mortality, the AAF for morbidity from non-motor vehicle accidents was multiplied by 9/4 and the AAF for morbidity from motor vehicle accidents was multiplied by 3/2. These multiplication factors were based on two studies that compared blood alcohol levels of emergency room patients, where the blood alcohol levels were obtained from coroners' reports of patients who died from an injury (Cherpitel, 1994, Cherpitel, 1996).

For women, a continuous RR function is only available for the morbidity of non-motor vehicle accidents. The morbidity AAF for motor vehicle accidents for women was calculated by multiplying the morbidity AAF for motor vehicle accidents for men by the product of the *per capita* consumption of alcohol for women divided by the *per capita* consumption of alcohol for men. This imputation method was performed since the RR function for motor vehicle accidents is considered valid for men only (Shield et al., 2012a). The mortality AAFs for both motor vehicle and non-motor vehicle accidents follow the methodology for men.

2.4 Calculating uncertainty

AAFs are complex based on many different indicators. Thus, we had to develop our own procedure for uncertainty (Gmel et al., 2011b). We followed a Monte Carlo type approach to estimate the variance by sampling the AAFs with randomly generated samples of its parameters (for a description of this method, see (Kroese et al., 2011)). The main variables of the AAF functions are the risk relations and the prevalence, each composed of their own coefficients and parameters. In order to estimate the variance of the AAFs, 100'000 sets of lowest level parameters are randomly generated according to their distributions (a lowest level parameter is the basic coefficient of parameter on which the relative risk functions and distributions depend). The AAF functions are then evaluated for each set of variables yielding 100'000 samples of each AAF. The variance of these samples reflects the true variance of the AAF as long as the sample size is large enough.

2.5 Age-standardization of rates

Rates were directly age-standardized (Rothman et al., 2008) to the age structure of the 2011 population of Switzerland. Given the relative short time interval and that the age-standardization was used to the same

population of Switzerland, this standardization method was sufficient and its results much easier to interpret than more complicated methods (Lee and Liaw, 1999).

2.6 Statistical software

All calculations to derive AAF were implemented using the statistical software package R version 2.11.1 (R. Development Core Team, 2011). The program and the program description is provided on a CD or can be obtained from the authors. The number of alcohol-attributable deaths and years of life lost were calculated using SPSS version 20.

3 Alcohol-attributable mortality in Switzerland in 2011

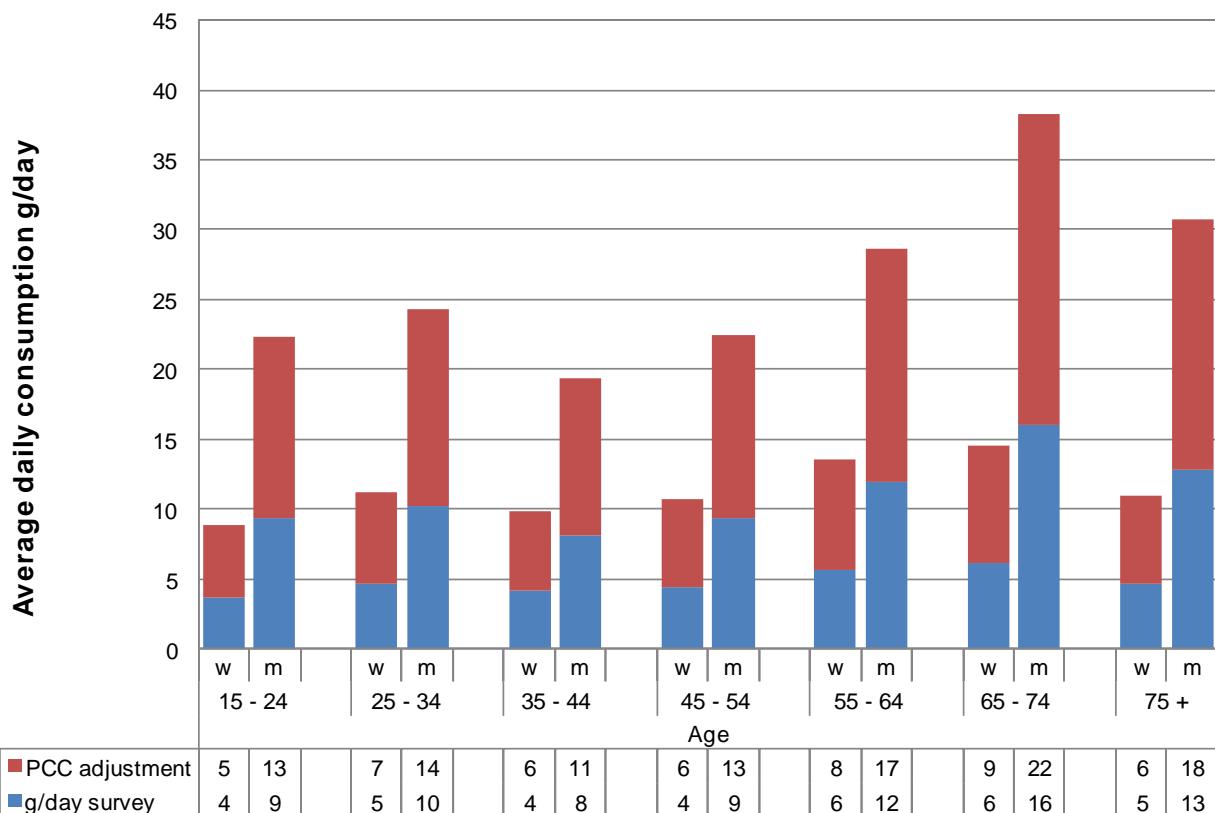

3.1 Alcohol consumption in 2011

Switzerland is part of Europe (the region of the world where the most alcohol is consumed). While there are differences within Europe, almost all European countries consume 50% (or more) more alcohol when compared to the global average (World Health Organization, 2011). In 2011 Switzerland had an adult *per capita* consumption of 10.5l of pure alcohol, of which 0.5l is estimated to be unrecorded consumption (the global average adult *per capita* consumption for 2010 is estimated to be 5.5l (Shield et al., 2013); the Swiss numbers were taken from the Swiss Alcohol Board and the GISAH – see above).

Overall, the majority of Swiss consumed alcohol during the last year, more than 90% of men, and about 85% of women (see Appendix Table A1.1).¹ The average consumption as indicated by survey data alone was about 10.6g pure alcohol per day for men 15 years and older, and 4.7g pure alcohol for women in this age group (including abstainers and former drinkers see Appendix Table A1.2 for alcohol users only). The age pattern is different from many English-speaking countries, as mean consumption peaked in the age group 65 – 74 years of age (see Appendix Table A1.2, and Figure 1). Otherwise, we see the well-known pattern that in all age groups, men consume more than women, which holds for almost any country in the world (World Health Organization, 2011).

¹ Please note that all numbers on consumption are based on the population. Thus, they do not represent the means as reported by the survey, but the means weighted by population size.

Figure 1: Average daily consumption of alcohol in g/day by sex and age including lifetime abstainers and former drinkers, adjusted for PCC – Switzerland 2011

Remark: The sum of the g/day as measured by surveys and per capita consumption (PCC) adjustment adds up to g/day adjusted for PCC. For a description of the PCC adjustment-method see section 2.2

Concerning binge drinking occasions, two measures were used. The prevalence of at least monthly binge drinking was 25.7% for men and 12.3% for women aged 15+ years, with a decreasing trend by age (for details see Appendix Table A1.3). Besides the importance of monthly binge prevalence for ischaemic heart disease, the annual frequency of bingeing has been used for estimation of AAFs for injuries. On average, male bingers had 41 bingeing days per year and women had 31 (for details see Appendix Table A1.4). Overall, frequency of bingeing was higher among men compared with women.

4 Alcohol-attributable mortality in 2011

Why did we restrict ourselves to age groups 15-74?

In Switzerland in 2011, we estimated that 3'344 people died and 661 deaths were prevented due to alcohol consumption, resulting in a net death toll of 2'683 (4.3% of the population mortality). In the following we will only report alcohol-attributable mortality for the age groups 15-74. The underlying reasons for this restriction are threefold:

- While cause of death information are inevitably biased (James et al., 1955, Shojania et al., 2003), this bias increases substantially for death certificates for people of older age (Harteloh et al., 2010), and especially for the oldest age groups (age 80 and above, see (Alpérovitch et al., 2009)).
- Second, there is not only bias, but systematic bias, with cardiovascular diseases and ischaemic heart disease being the most generally used and overused category (Alpérovitch et al., 2009, Lahti and Penttilä, 2003, James et al., 1955). Unfortunately, the beneficial effects of alcohol are concentrated in these categories, leading to a systematic overestimation of alcohol-attributable ischaemic heart disease deaths avoided but also caused (depending on drinking patterns and lifetime or former drinking rates) in older age categories.
- Third, the relative risks for alcohol-attributable causes tend to decrease with age (Klatsky and Udaltsova, 2007). As a result, the consequences of consumption, both detrimental and beneficial, tend to be exaggerated in the older age groups when age-unspecific relative risks from meta-analyses are used as is commonly the case (and none of the meta-analyses above had age-specific RR information). As indicated above, we tried to mitigate against this effect by using age-specific RR functions for ischaemic diseases.

In sum, we were only able to correct for one of three potential errors in estimating alcohol-attributable deaths of the older age groups, and thus will concentrate on age groups 15-74 as the main results. Of course, all results including the ones for the oldest age group are part of the Appendices. In addition, the exaggerating effect of cardiovascular disease in general, and particularly ischaemic heart disease, will be demonstrated in chapter comparing trends of alcohol-attributable mortality.

Alcohol-attributable mortality by sex and age

Overall, alcohol-attributable mortality in Switzerland in 2011 for 15-74 year olds amounted to 1'600 net deaths (95% C.I. 1'472 -1'728; see Appendix Table A6.1), with 1'768 deaths being detrimental and 168 death being avoided. For more details see Table 2 (for AAF, alcohol-attributable deaths and total deaths in 2011 see Appendix Tables A2.1 – A2.4).

Table 2: Alcohol-attributable mortality in Switzerland for 2011 by sex, 15-74 year olds

	Women	Men	Total
Alcohol-attributable beneficial effects (avoided deaths)	-42	-126	-168
Alcohol-attributable detrimental (deaths caused)	461	1'307	1'768
Alcohol-attributable net effect (deaths caused)	419	1'181	1'600
Total deaths in alcohol-attributable categories ¹	2'853	5'251	8'104
Average AAF for these categories	14.7%	22.5%	19.7%
Total deaths	6'936	11'550	18'486
Proportion of deaths attributable to alcohol	6.0%	10.2%	8.7%

Remark¹: Number of deaths fully or partly attributable to alcohol.

This means, that more than every 12th death in adults up to and including 74 years of age in Switzerland was caused by drinking alcohol, about every 10th death in men, and more than every 17th death for women. Alcohol consumption thus continues to be major risk factor for mortality in Switzerland.

Analysing these deaths further, the relative impact of alcohol on mortality is biggest in younger ages (see Figure 2), highest in the age group 25-35. Thus the absolute number of deaths and the proportion of alcohol-attributable deaths to overall deaths have trends in the opposite direction. Obviously, with age, alcohol-attributable deaths increase, which is mainly based on the fact that the death rates increase with age. However, the proportion of all deaths attributable to alcohol is highest in younger ages, again underlining the public health importance of alcohol. Alcohol-attributable deaths come earlier in life, on average at age 57.5 for men and age 59.3 for women. Thus, the average age for alcohol-attributable deaths is lower than the average age of death for the age group, which is 60.9 for men and is 61.5 years for women; i.e. more than 3 respectively 2 years higher. This average age of an alcohol-attributable death is also much younger than for most other risk factors, for instance tobacco (for the age structure of deaths attributable to different risk factors see (Lim et al., 2012)).

Figure 2: Deaths due to alcohol consumption by age group and sex for 15-74 year olds, for Switzerland 2011

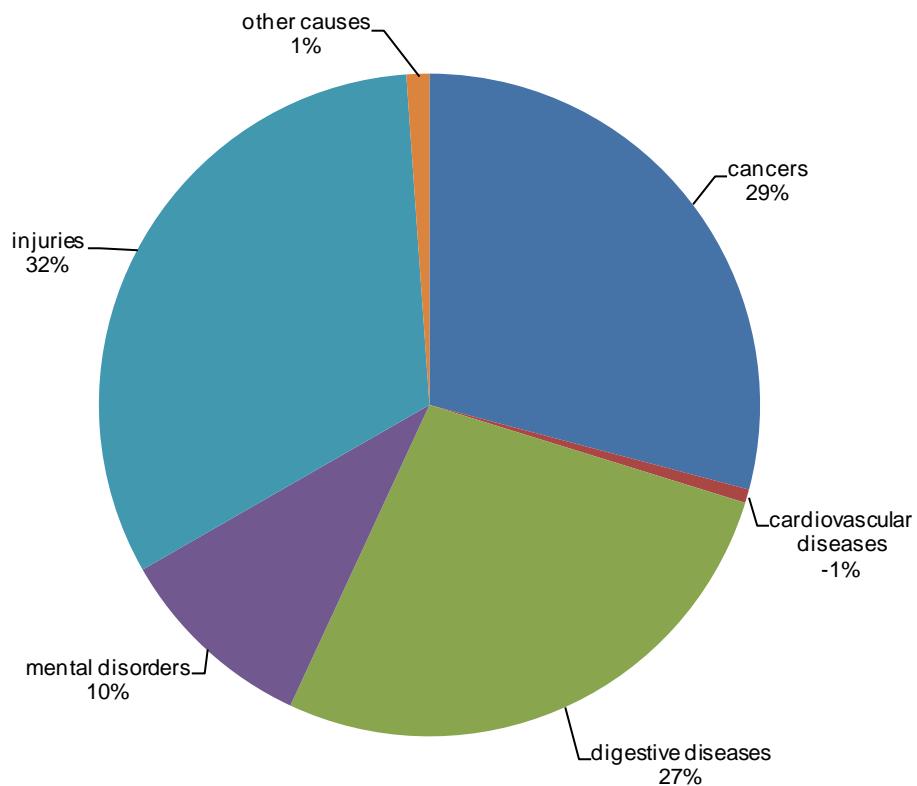

Remark: Dotted lines refer to the proportion of deaths attributable to alcohol within all deaths (for details see Appendix Tables A2.12 and A2.13)

Causes of death underlying alcohol-attributable deaths

Figure 3 gives a quick overview of the different broad causes of death (for details see Appendix Tables A2.11 and A2.17).

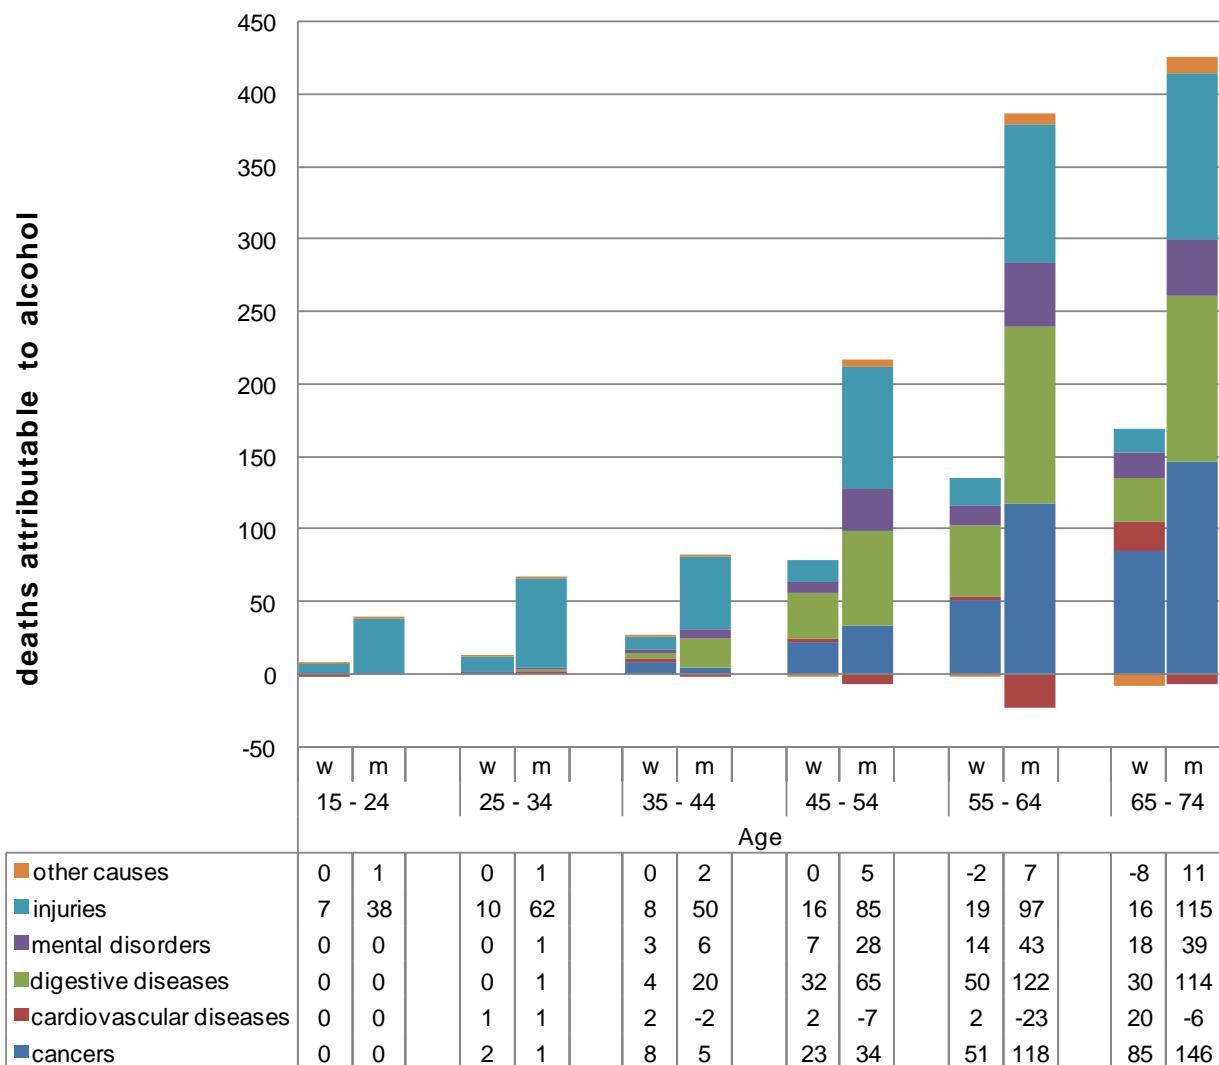

Figure 3 Alcohol-attributable deaths in 2011 by broad causes – 15-74-year-olds

Overall, in the age group of 15-74 year olds, injuries, cancers and digestive diseases make up around 90% of all deaths.

Figure 4 shows, that alcohol-attributable causes of death vary markedly by age groups.

Figure 4: Broad causes of alcohol-attributable causes of death by age and sex, 15-74 year olds for Switzerland, 2011

The Figure 4 displays net deaths, and thus masks the substantial impact of alcohol consumption on cardiovascular mortality in ages 45 to 74. The numbers for cardiovascular deaths in Figure 4 in the age categories 15-54, 55-64 and 65-74 are 3, -21 and 14, respectively, composed of 22, 28 and 81 deaths caused by alcohol consumption, and 25, 49 and 67 deaths avoided by alcohol, respectively. However, even these numbers underestimate both deaths caused and avoided, as they are calculated based on net deaths by disease category, and within several disease categories, there are detrimental and beneficial deaths cancelling out.

As indicated above, the impact of alcohol consumption on cardiovascular event is complex (for overviews see (Puddey et al., 1999, Roerecke and Rehm, 2012a)), and in Switzerland the detrimental effects on hypertension, haemorrhagic stroke, alcoholic cardiomyopathy, conduction disorders, other dysrhythmias, and partly ischaemic stroke cancel out the beneficial effects of regular and light to moderate drinking on ischaemic disease.

Another important aspect of Figure 4 is the change of composition in alcohol-attributable deaths. In the age groups 15-34, alcohol-attributable deaths are almost entirely composed of injury, the majority of which are

self-inflicted (see Appendix Table A2.4). Then the picture gradually shifts to include more digestive diseases (mainly liver cirrhosis) and later in lifetime cancers.

Looking at more fine-grained "single" top 3 causes across age, self-inflicted injuries, motor vehicle accidents (only among men) and other unintentional injuries are the main causes of death among the younger age groups (see Table 3). Breast cancers among women, liver disease (alcoholic liver cirrhosis), and oral cavity and pharynx cancers (among men) become more prominent among the older population segments.

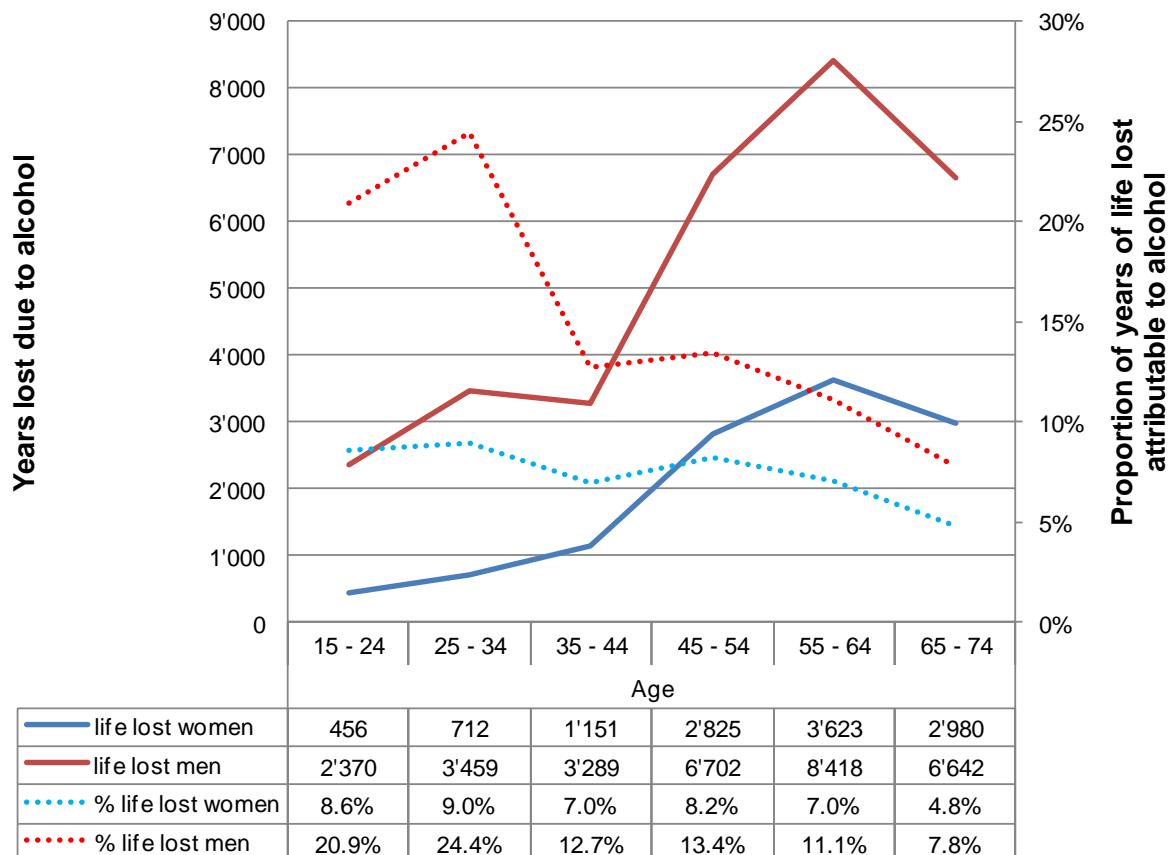

Table 3: Single most important causes of death by sex and age in Switzerland, 2011

Age	Condition	Women N	Men Condition	N
15-24	self inflicted injuries	2	self inflicted injuries	13
	other unintentional injuries	1	other unintentional injuries	12
	other 100% alcohol attributable	1	motor vehicle accidents	11
25-34	self inflicted injuries	5	self inflicted injuries	27
	other unintentional injuries	2	other unintentional injuries	18
	breast cancer	1	motor vehicle accidents	8
35-44	breast cancer	7	self inflicted injuries	23
	liver disease	4	liver disease	20
	self inflicted injuries	4	other unintentional injuries	12
45-54	liver disease	32	liver disease	64
	breast cancer	16	self inflicted injuries	39
	self inflicted injuries	8	mental disorder due to use of alcohol	28
55-64	liver disease	50	liver disease	120
	breast cancer	33	oral cavity and pharynx cancer	56
	mental disorder due to use of alcohol	14	self inflicted injuries	45
65-74	breast cancer	50	liver disease	110
	liver disease	29	self inflicted injuries	46
	mental disorder due to use of alcohol	18	oral cavity and pharynx cancer	43
total	liver disease	115	liver disease	315
	breast cancer	107	self inflicted injuries	193
	mental disorder due to use of alcohol	42	mental disorder due to use of alcohol	117

Alcohol-attributable years of life lost in 2011

Years of life lost (YLL) due to premature mortality are a time-based measure more relevant for public health than pure death counts (for summary measures of health see (Murray et al., 2000, Gmel and Rehm, 2006)), as most societies make special efforts to prevent premature deaths. Figure 5 shows number and proportion among all YLLs attributable to alcohol (for details see Appendix Table A2.5).

Figure 5: Alcohol-attributable years of life lost by age group and sex for 15-74 year olds, for Switzerland 2011

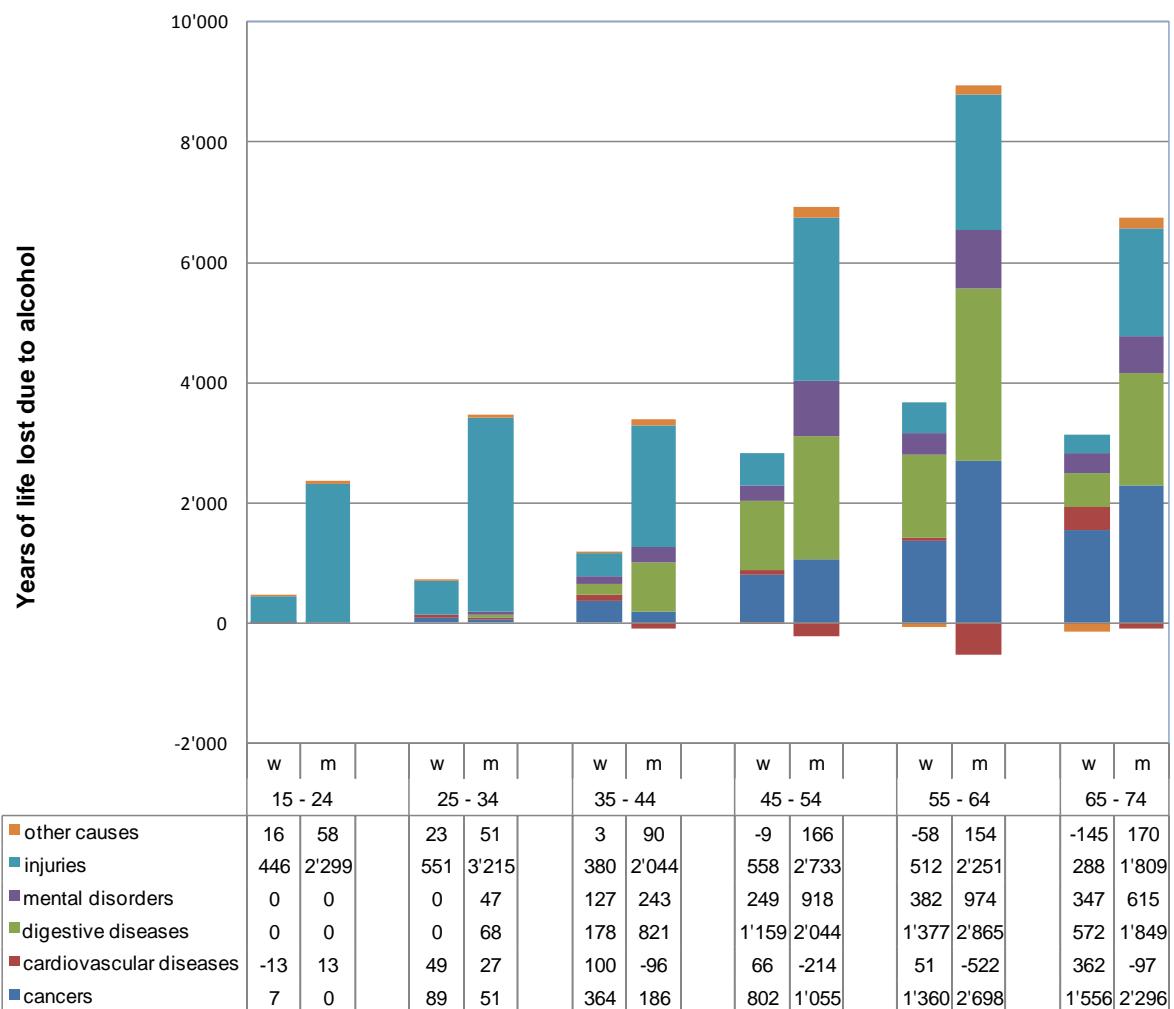

Remark: Dotted lines refer to the proportion YLL attributable to alcohol within all YLL (see Appendix Table A2.6 and A2.15/A2.16)

Similarly to mortality, the YLLs increase in total number for older age categories but their proportional weight, compared to all YLLs in a given age group decreases. The absolute number of YLLs decreases in the oldest age group for the obvious reason that the amount of years left to live in this category is inherently smaller than in the other ones.

The broad causes for alcohol-attributable YLLs are summarized in Figure 6 (for details see Appendix Tables A2.14 and A2.18)

Figure 6: Broad causes for YLLs by sex and age, 15-75 years old, for Switzerland 2011

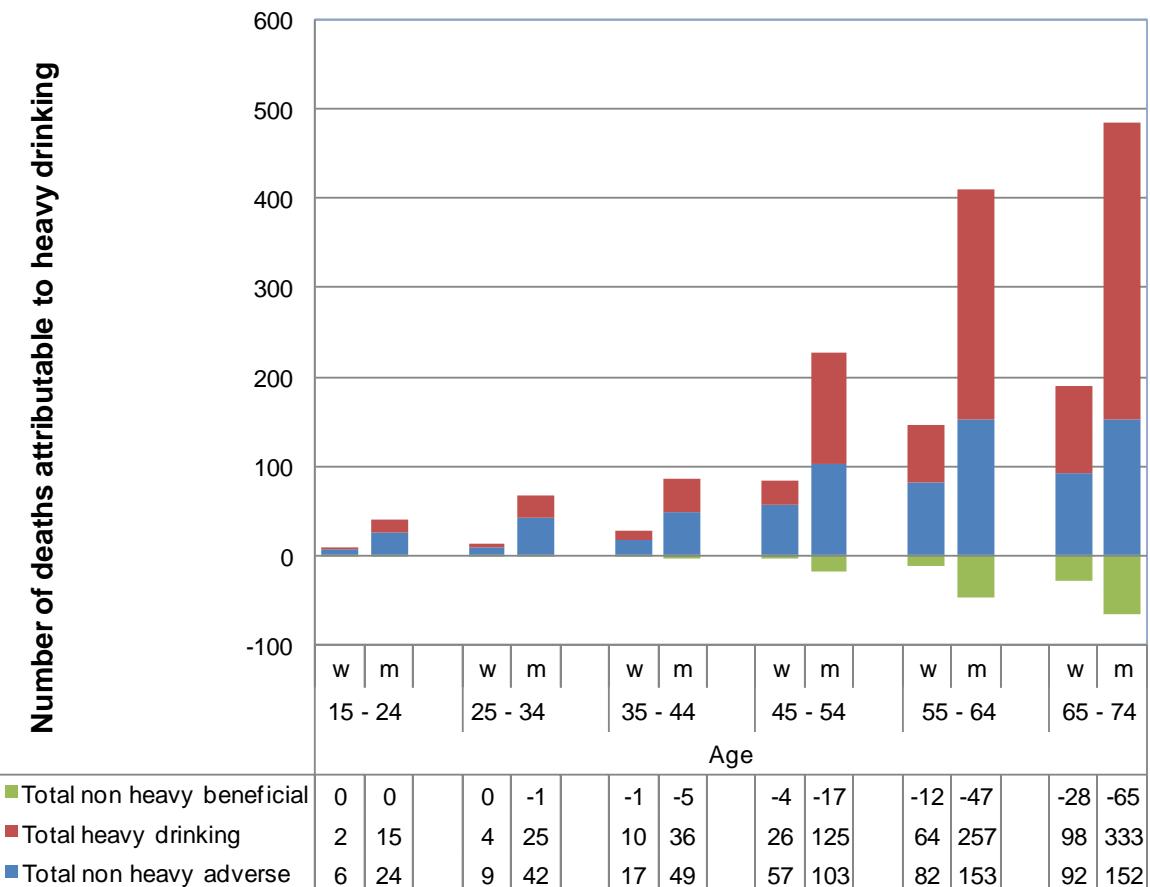

Not surprisingly, as both measures are related, a similar distribution over the lifespan as for deaths appears with injuries dominating early adulthood, and then liver cirrhosis (in digestive diseases) and finally cancers. Overall, 42,627 years (men: 30'880; women: 11'747) of life are lost by premature death until 74 years of age. Compared with number of alcohol-attributable deaths (Figure 4), differences in YLL across age groups are less pronounced logically, as in younger age groups each death accounts for more YLL than a death in older age groups.

4.1 The role of heavy drinking

Overall, 62% of the net deaths are attributable to heavy drinking as defined by 40 g/day or more for women and 60 g/day or more for men or 56% of all the detrimental deaths. The proportion was larger for men (67% respectively 60%) than for women (48% respectively 44%). In other words, the majority of alcohol-attributable deaths among 15-74 year olds in Switzerland had been caused by heavy drinking (see Figure 7, for details see Appendix Tables A2.7 to A2.10).

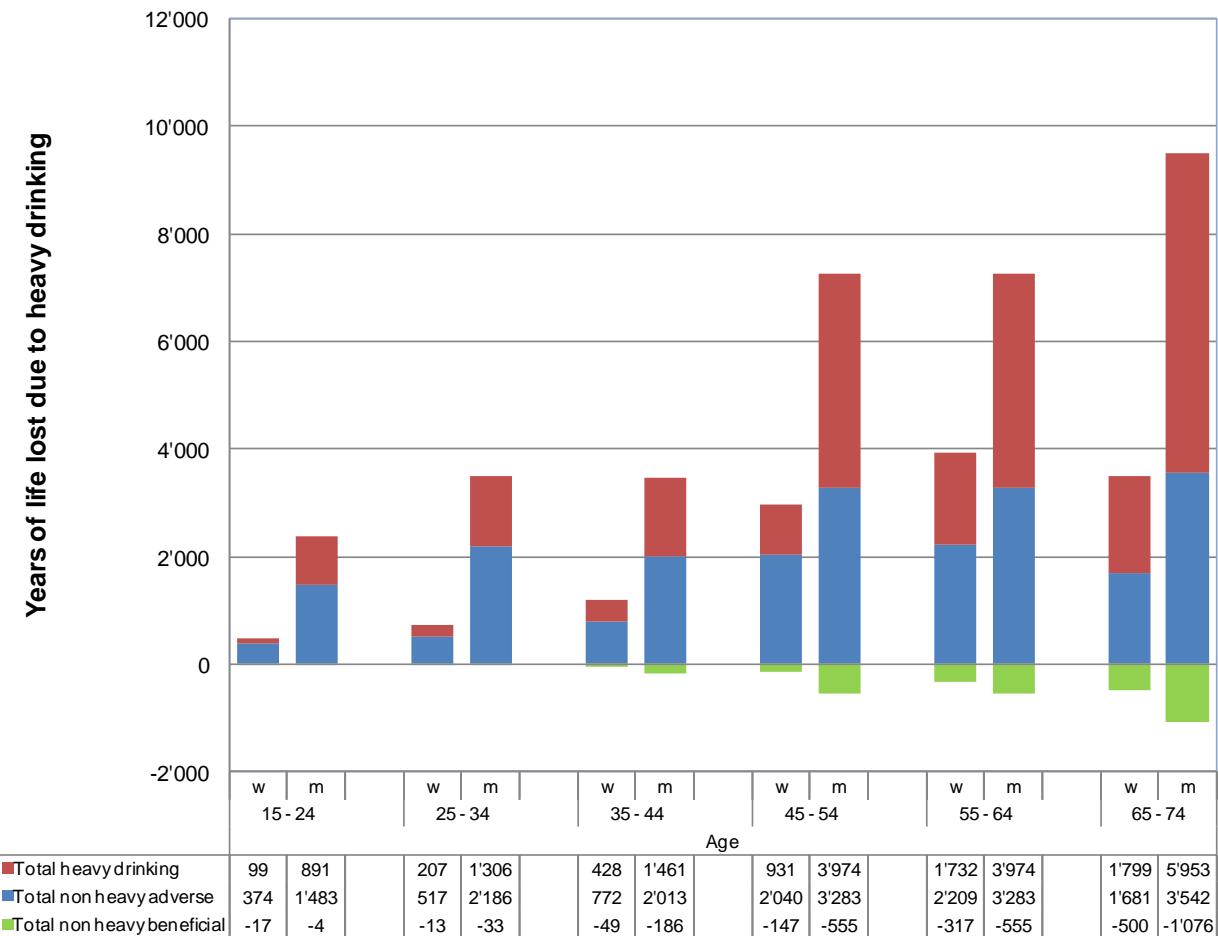

Figure 7: Deaths by heavy drinking

Remark: All beneficial effects had been caused by non-heavy drinking

This result is similar to the results from other European countries (Shield et al., 2013, Rehm et al., 2012). Looking at the YLL, we see even slightly lower proportions (see Figure 8), mainly due to two facts: a) the beneficial effects attributable to alcohol are relevant only in older ages, and thus related to less YLL, b) in younger ages, where each death provides more YLL, the impact of heavy drinking is less pronounced, as young drinkers are more often binge drinkers than chronic heavy drinkers.

Figure 8: Years of life lost by heavy drinking

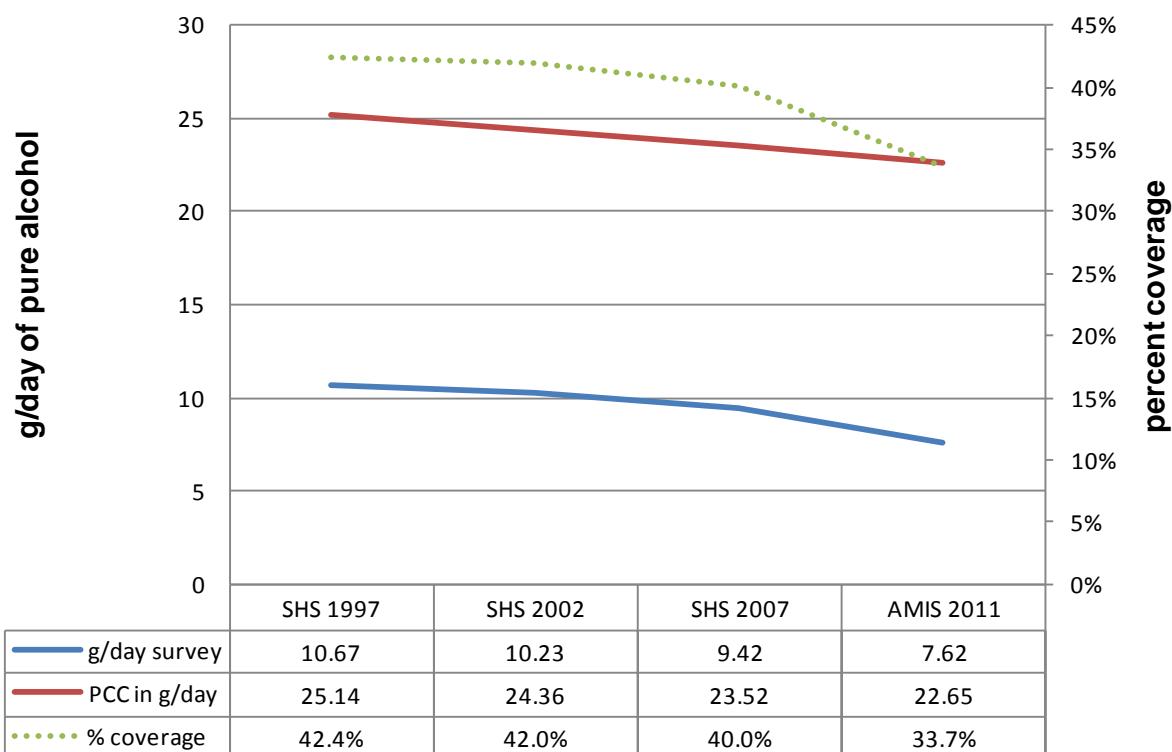

Remark: All beneficial effects had been caused by non-heavy drinking

5 Changes in drinking between 1997 and 2011

Alcohol consumption declined in the time period studied, both based on survey data and on sales data. Figure 9 gives an overview.

Figure 9: Average level of alcohol consumption in Switzerland as measured by survey and sales data

Interestingly, survey-based alcohol consumption went down by almost 30%, whereas *per capita* consumption went down by about 10% (see Figure 9). As a consequence, the coverage, defined as the proportion of *per capita* consumption which would be covered by aggregating the survey responses, went down as well. This seems to be a common phenomenon in high-income countries, where the coverage rates no longer seem to reach the averages as described some decades ago (Midanik, 1988, Midanik, 1982b). While this indicates that alcohol research may have to rethink their monitoring, it would lead too far to discuss this phenomenon further in this report. Interestingly, this does not necessarily mean that the people with highest consumption disproportionately underreport their consumption. There is even evidence of overreporting of consumption in people with alcohol use disorders (Midanik, 1989, Midanik, 1982a), so the overall lack of coverage may be more linked to failure to include populations with heavy drinking into the sampling (see also the discussion of (Rehm et al., 2007, Rehm et al., 2010b, Shield and Rehm, 2012)). Finally, it should be noted that we do not expect that 100% of the sold beverages will be consumed, as some alcohol is spilled or left in containers (this is estimated to be less than 10%, however).

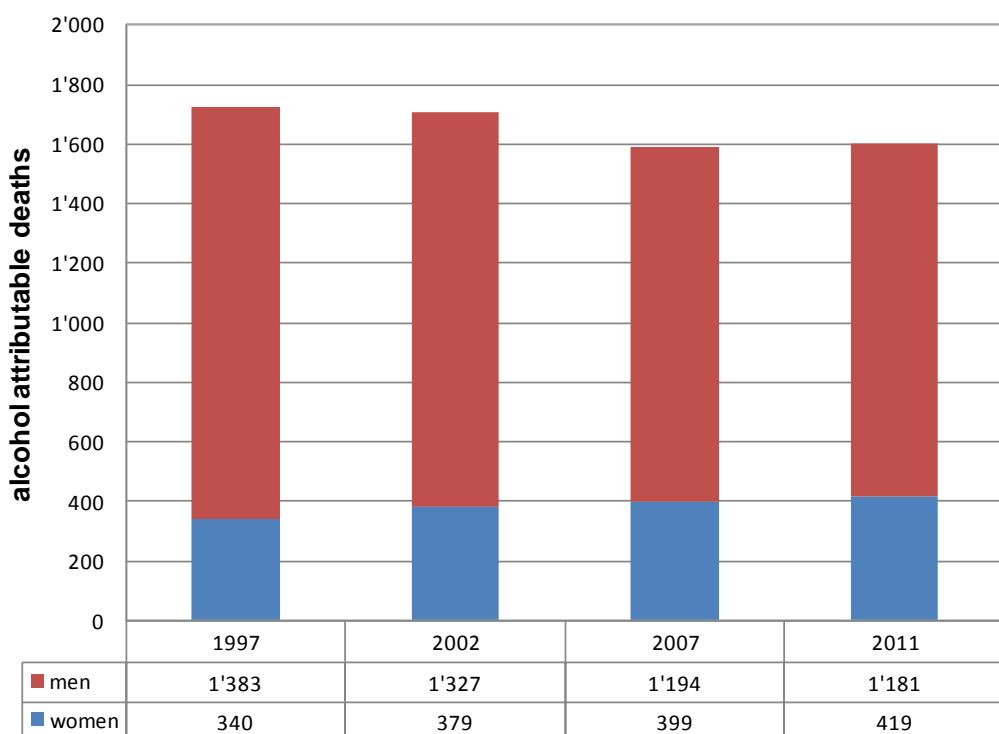

6 Trends in alcohol-attributable mortality 1997-2011

6.1 Overall trend for alcohol-attributable mortality

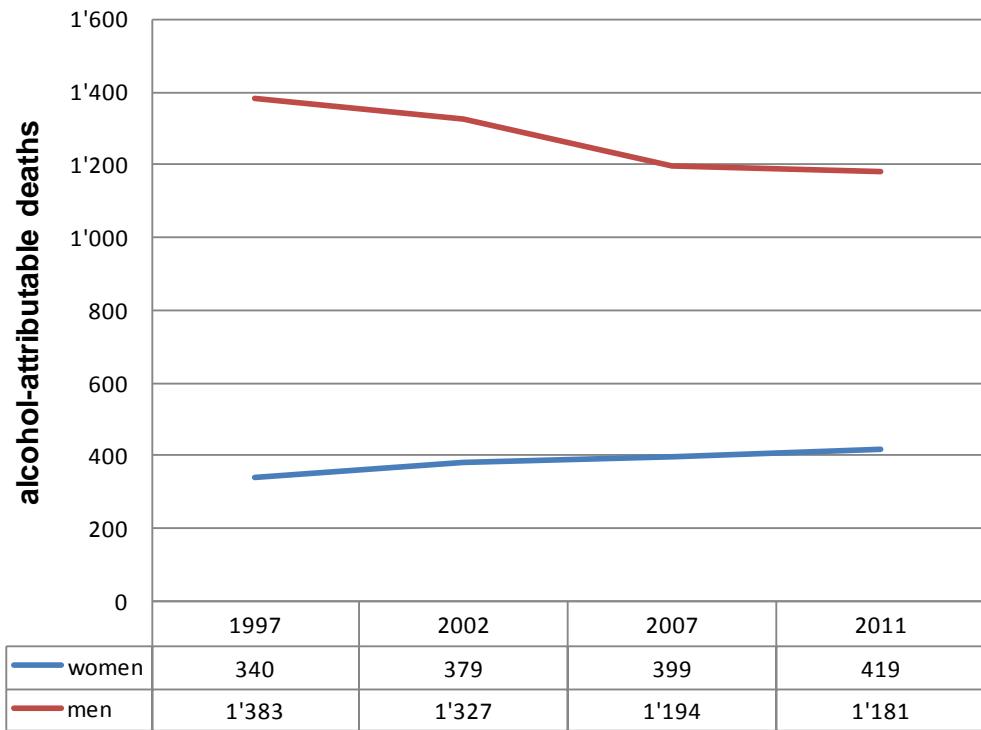

Overall, alcohol-attributable mortality is high in Switzerland with every 10th death in men and every 17th in adult women under age 75 being attributable to consumption of this substance (for European comparison see (Shield et al., 2013) and (Rehm et al., 2012); for global comparisons see (World Health Organization, 2009, Rehm et al., 2009a)).

However, did alcohol-attributable mortality go up or down in the last 15 years? Monitoring should be able to answer such questions, and given the unique comparable set of exposure and mortality measures actually make the detection of such trend possible. A first look at the net numbers of alcohol-attributable mortality for the years examined indicates few changes (Figure 10, see details for 2007 Appendix Tables A3.1 to A3.11; for 2002 Appendix Tables A4.1 to A4.11; for 1997 Appendix Tables A5.1 to A5.11).

Figure 10: Absolute numbers of alcohol-attributable deaths by sex, 1997-2011, 15-74 years old

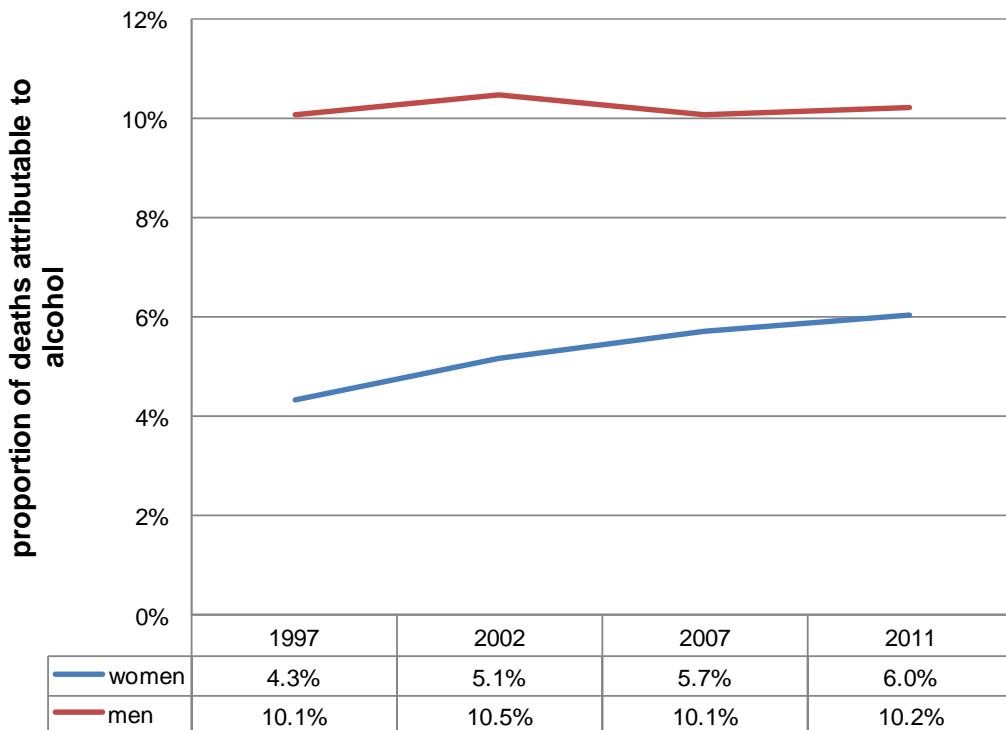

However, if the same data are displayed differently, there seems to be an indication that alcohol-attributable deaths in women go up and men go down, with men dominating the total picture (Figure 11). Both the total reduction in death ($\chi^2=8.54$, $df=3$, $p=0.037$) and the gender-specific differences ($\chi^2=23.61$, $df=3$, $p < 0.001$) are significant. Note there are similarly decreasing trends in life years lost (see Appendix Tables A2.5, A3.5, A4.5, A5.5).

Figure 11: Trends in absolute numbers of alcohol-attributable deaths by sex, 1997-2011

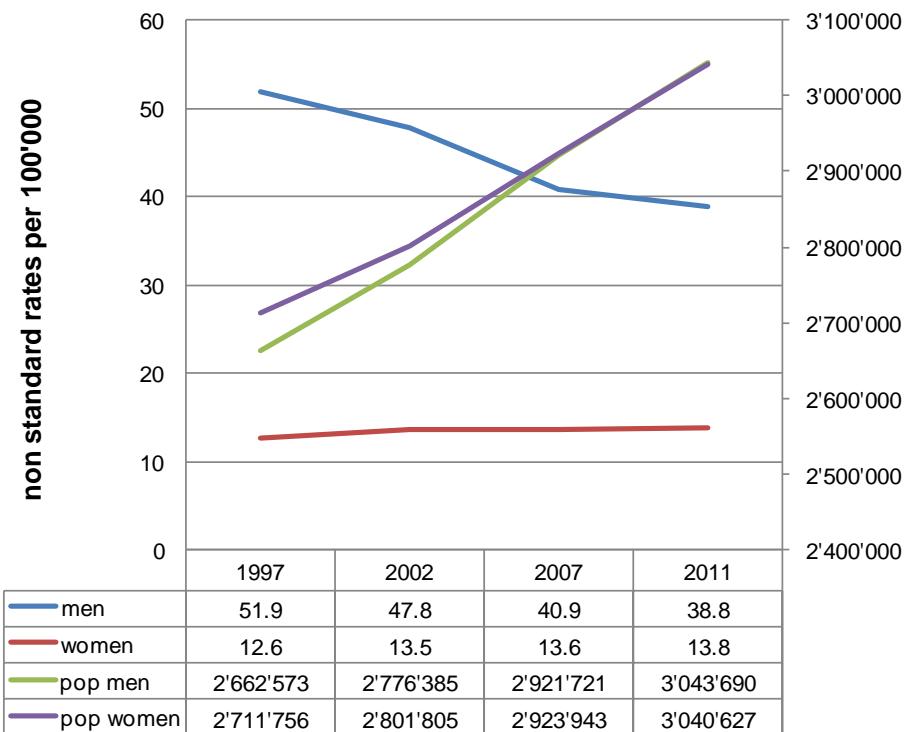

What does this mean? Absolute numbers of alcohol-attributable deaths depend on a variety of potential influences, such as the overall number of deaths in Switzerland and exposure of alcohol. The former can only meaningfully be interpreted, when we know the trends in mortality and the population size, plus the distribution of deaths over different age categories. As the next step, we look into the proportion of all deaths which is attributable to alcohol (see Figure 12), which controls for trends in overall mortality.

Figure 12: Trends in proportion of alcohol-attributable deaths among all deaths by sex, 1997-2011

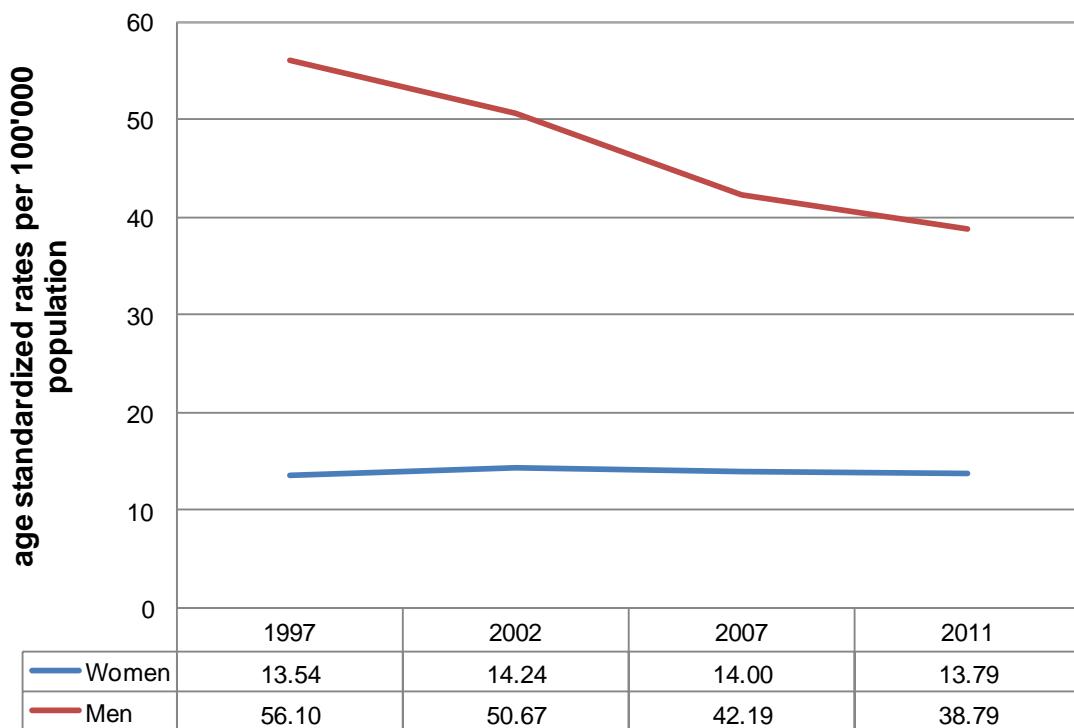

The proportion of all deaths is stable for men, but increases for women. However, this statistic still does not give us a clear view of the potential impact of trends in population size and death rates per population size. The effect can be seen in Figure 13. Clearly, there is a decrease in male alcohol-attributable mortality over time, whereas in women the rates seem to be more or less stable, maybe going up a little.

Figure 13: Trends in crude rates of alcohol-attributable deaths per 100'000 population by sex, 1997-2011

The final effect, which has to be controlled for are trends in population composition over time, i.e. taking into account the effect, that the Swiss population becomes older over time. This can be accounted for in age-standardized rates. To ease interpretation, we standardized all ages to the population distribution of 2011, i.e., we statistically adjusted the data as if alcohol-attributable deaths as well as overall deaths happened in populations with an age distribution of 2011. Figure 14 shows the result: comparable age-standardized rates of alcohol-attributable deaths in Switzerland for the population between 15 and 74 years of age.

Figure 14: Trends in age-standardized rates of alcohol-attributable deaths per 100'000 population by sex, 1997-2011

While we again see a clear trend, that alcohol-attributable death rates decline between 1997 and 2011 in men, the rates for women remain stable. In other words, the results from the crude rates are confirmed in general, but it becomes evident, that the slight upward trend for women using the crude standardization is only due to shifting age composition over the years.

How can these trends be interpreted? For men, the proportion of alcohol-attributable deaths among all deaths was pretty stable (see Figure 12 above), so the decline in rates over the past 15 years just reflect the overall decline in mortality rates and the associated increase in life expectancy. The trend for alcohol-attributable deaths did not behave any different than the trend for all deaths.

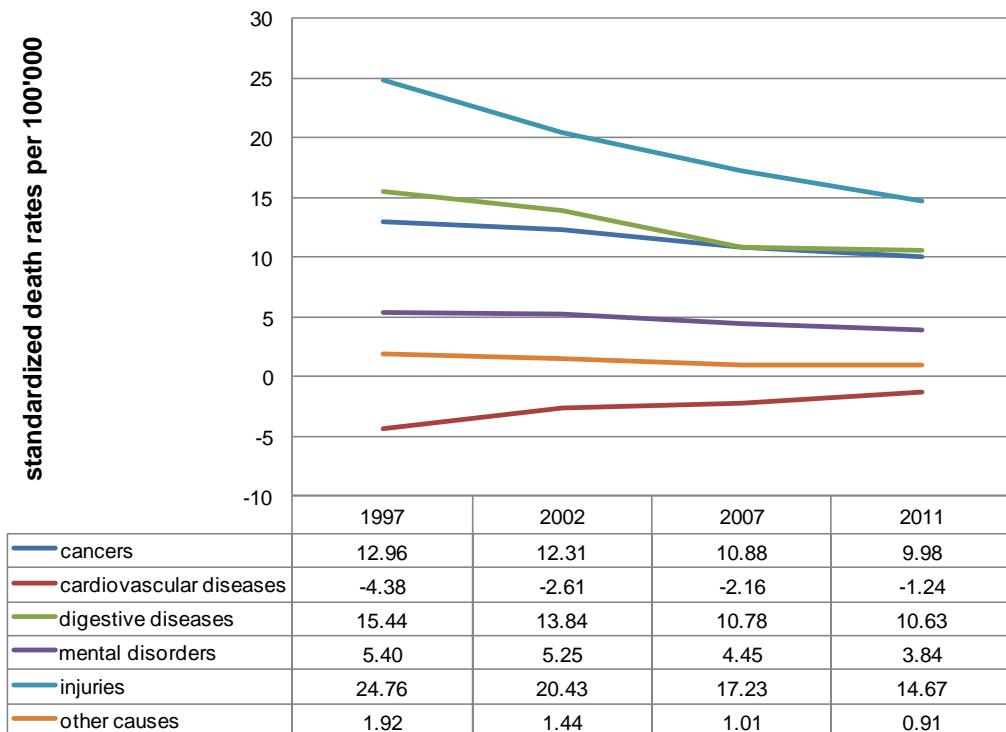

For women, however, while overall mortality rates decreased, the proportions of alcohol-attributable deaths increased, with the net result, that the population rates of alcohol-attributable deaths remained stable. In other words, the relative impact of alcohol on female mortality has grown in the past 15 years, and alcohol is slowing down the general trend of an increase in life expectancy in Swiss women.

6.2 Underlying changes in causes of death

In the following, we will examine trends in causes of death underlying the above-described declining trend in alcohol-attributable mortality. Figure 15 and 16 show the cause-specific development over time. Clearly, injuries contributed the most to the decrease in alcohol-attributable death rates among men with a 41% decline (the underlying absolute numbers also went down from 639 alcohol-attributable injury deaths in 1997 to 446 in 2011), more than digestive disease categories (-31%) or mental disorders (-29%). Cancers stayed relatively more stable (-23%), meaning that its rates basically developed very similar to the general decline of death rates in Switzerland. The one disease category, which developed counter to the general trend were

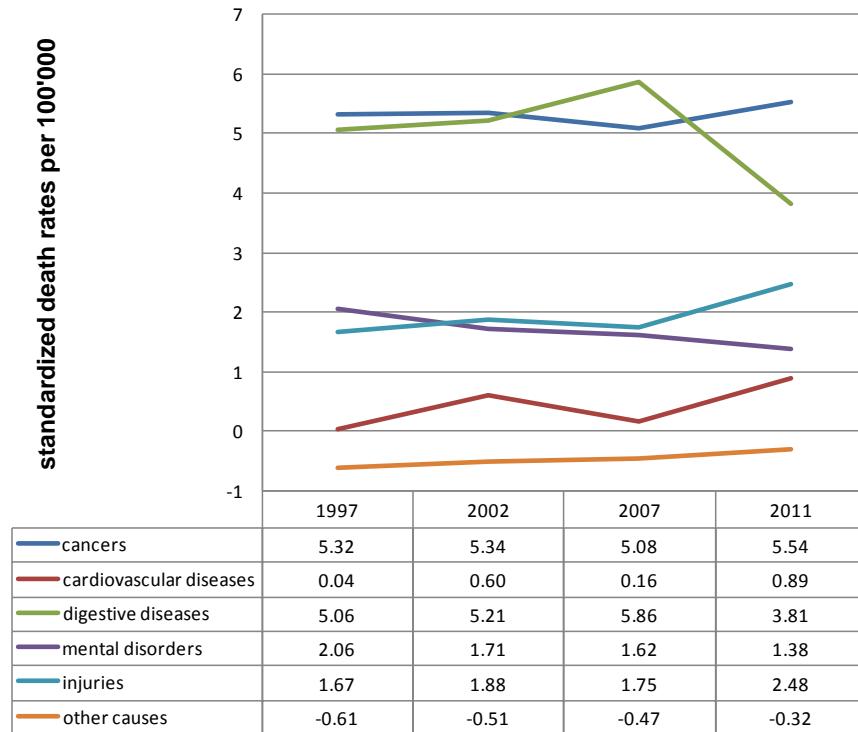

cardiovascular diseases. Over time, the overall protective effect by alcohol consumption on these disease categories diminished more and more.

Figure 15: Trends in alcohol-attributable death rates per 100'000 1997-2011, men 15-74

Among women alcohol-attributable mortality rates stayed more stable than among men. There were some changes between 2007 and 2011 (e.g. decrease in digestive disease mortality and increase in cardiovascular disease and injuries), but they canceled each other out and were based on much smaller absolute numbers of deaths.

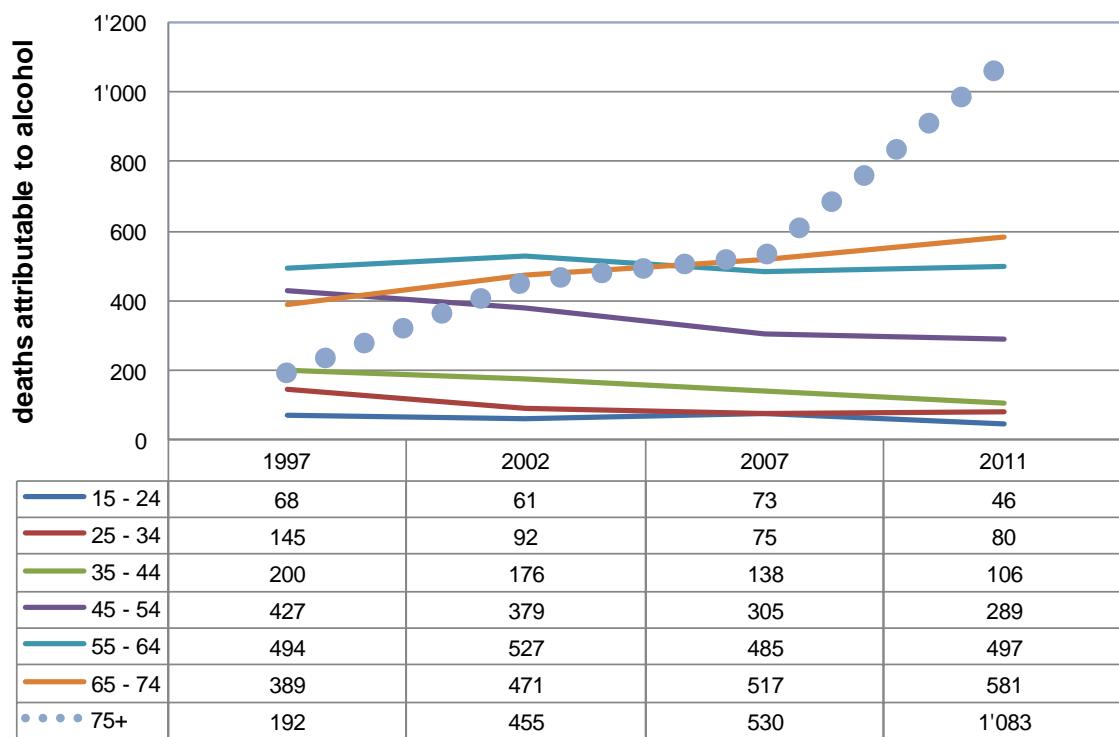

Figure 16: Trends in alcohol-attributable death rates per 100'000 1997-2011 women 15-74 years old

6.3 Excursion: What happens in the oldest age group?

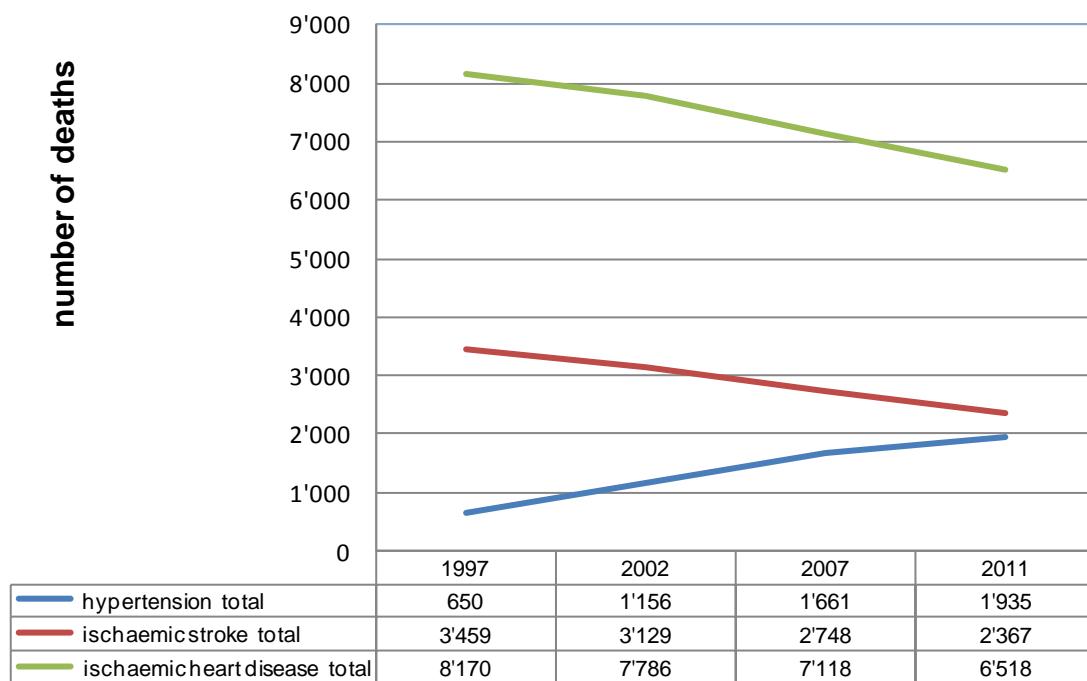

There is an anomaly in the data for the older age groups. Whereas all other age groups display relatively stable numbers of death over the time period examined, for ages 65+, and especially for the oldest age group, there is a trend to increase death (see Figure 17). This trend among the oldest would overshadow trends in the population of 15-74 year olds. There are around 900 more alcohol-attributable deaths between 1997 and 2011 stemming from this age group alone.

Figure 17: Trends in absolute numbers of alcohol-attributable deaths by age category 1997-2011

Behind this sudden increase in alcohol-attributable deaths in the oldest age groups seems to be mainly a shift in the distribution of the cardiovascular causes of death: hypertension had been increasing whereas ischaemic heart disease went down over the past 15 years in Switzerland (see Figure 18). Given that alcohol has almost exclusively detrimental effects on hypertension (Taylor et al., 2009), whereas the impact on ischaemic heart disease is mainly beneficial except for current binge drinkers and former drinkers ((Roerecke and Rehm, 2012b); for the detrimental impact of bingeing see (Roerecke and Rehm, 2010); for former drinkers see (Roerecke and Rehm, 2011), and for ischaemic stroke mixed (Patra et al., 2010)), this means on the one hand a reduction of the beneficial effect and on the other hand an increase of the detrimental effects of alcohol.

Figure 18: Trend in selected cardiovascular cause of death diagnoses in Switzerland for 75+ year olds, 1997-2011

At this point, we do not know, if we are facing a shift in cause of death attribution practices, or if this change is real, i.e., that hypertensive deaths have been de facto increasing whereas ischaemic causes of death have been decreasing in the older age categories. And if the latter is the case, whether the high alcohol consumption played a role here. Certainly, given the number of deaths affected, this would deserve more research using more sophisticated methods of determining the cause of death such as autopsies.

7 Discussion

Overall, we see a decline in alcohol-attributable mortality rates in men (15-74 years old) of about 30% and basically no change in women (the same age category of 15-74 years). In the following, both trends will be examined in detail.

7.1 Changes in alcohol-attributable mortality rates in men

As we have seen above, for men the absolute number of alcohol-attributable deaths decreased by about 15% to a much smaller degree (see Figure 11 above), and the proportion of alcohol-attributable death to all deaths remained constant (see Figure 12). How can this be explained?

The first element is the alcohol-consumption, which has decreased by 10% overall, and based on surveys more in men than in women. But this change cannot be the sole reason of the much more marked decline in the death rates. More importantly is the overall decrease in mortality rates in Switzerland, where the number of male deaths went down by 16% between 1997 and 2011, the population increased, resulting in a decrease of 34% in age-standardized rates of total mortality. There may be two reasons here:

- Swiss men live healthier lives, i.e., they have reduced unhealthy behaviours and increased healthy lifestyles.
- Immigration leads to more comparatively healthy people coming in (healthy immigrants effect; for examples see (McDonald and Kennedy, 2004, Gushulak et al., 2011)); comparatively to the people of same age and sex of the non-immigrant population. As Switzerland has had relatively high rates of immigration in the time period under examination with about 1/5 of the Swiss resident population now being immigrants (De Coulon et al., 2011), the healthy immigrant effect is relevant. This is especially true, as immigrants to Switzerland have relatively high level of education and are well integrated into the labor market (De Coulon et al., 2011); for the importance of these factors and economic status in general see (Malmusi et al., 2010)). Finally, the effect would be even stronger, if a large portion of people migrated out again after a few years, which is only partly the case in Switzerland.

Contrary to the above factors, the medical system does not contribute that noticeably to decreasing the mortality rates and increasing life expectancy (for Europe see (Zatonski et al., 2008, Zatonski et al., 2011)).

At this point, we do not have enough information to further quantify the various impacts of the above factors on alcohol-attributable mortality rates in Swiss men, but we suspect, a smaller effect of consumption reduction got amplified by other factors not related to alcohol consumption.

7.2 Changes in alcohol-attributable mortality rates in women

For women, the situation is completely different. Clearly, alcohol-attributable mortality increased as proportion of total mortality (see Figure 12). Even after taking into consideration that the overall mortality rates for women decreased by 26% between 1997 and 2011 in Switzerland for women 15-74 years of age, the age adjusted rate of alcohol-attributable mortality for women remained stable. In other words, alcohol contributed to the markedly slower increase of female life expectancy over the past 14 years. And this effect of alcohol of course could be seen despite the same environmental conditions with respect to immigration or overall lifestyle changes.

7.3 Conclusions for prevention

The improvement in alcohol-attributable mortality in men over the past one and a half decade should not obscure the fact, that alcohol consumption in Switzerland still is a major risk factor for mortality. After all, one in 10 deaths in the age group 15-74 in men and one in 17 deaths in women between ages 15 and 74 are due to alcohol. As the proportion of alcohol-attributable deaths in women increase, specific prevention efforts may be required for this group. In addition, the overall toll of alcohol-attributable mortality requires preventive efforts (World Health Organization, 2010, Anderson et al., 2009, Babor et al., 2010).

	non-binger	33.2	38.9	47.7	52.0	54.1	64.4	78.5	53.3
Remark:	for 2002 and 1997 bingeing prevalence were adapted from 2007 bingeing prevalence rates as only those for 8+ drinks or 5+ drinks were available for these years, which underestimates the frequency of binge drinking with 5+ or 4+ drinks.								

Table A1.4: Days of binge drinking (5+ for men and 4+ for women) per year among annual bingers (at least once a year)

Age	2007		2011	
	Women	Men	Women	Men
15-24	29.79	51.04	29.72	42.64
25-34	24.65	30.04	29.70	42.73
35-44	24.93	19.72	23.73	25.40
45-54	19.53	25.75	30.06	40.90
55-64	20.40	34.21	44.55	47.83
65-74	18.55	32.82	47.01	62.26
75+	32.74	38.11	42.49	57.77
total	23.94	31.93	31.35	41.35

Remark: for 2002 and 1997 frequencies of 2007 among binge drinkers were used as only those for 8+ drinks or 5+ drinks were available for these years, which underestimates the frequency of binge drinking with 5+ or 4+ drinks.

Table A1.5: Values of the continuous Relative Risk functions at 20/40/60/80 g/day

	Women				Men			
	20g/day	40g/day	60g/day	80g/day	20g/day	40g/day	60g/day	80g/day
oral cavity and pharynx cancer	1.66	2.56	3.71	5.04	1.66	2.56	3.71	5.04
oesophagus cancer	1.30	1.69	2.19	2.82	1.30	1.69	2.19	2.82
colon cancer	1.04	1.08	1.12	1.16	1.04	1.08	1.12	1.16
rectal cancer	1.07	1.15	1.23	1.32	1.07	1.15	1.23	1.32
liver cancer	1.15	1.31	1.48	1.65	1.15	1.31	1.48	1.65
larynx cancer	1.33	1.76	2.31	3.00	1.33	1.76	2.31	3.00
breast cancer	1.19	1.42	1.69	2.02	1.00	1.00	1.00	1.00
epilepsy	1.29	1.64	2.10	2.69	1.29	1.64	2.10	2.69
lower respiratory infections	1.10	1.21	1.33	1.46	1.10	1.21	1.33	1.46
hemorrhagic stroke	1.34	1.80	2.41	3.23	1.15	1.32	1.51	1.74
tuberculosis	1.00	2.96	2.96	2.96	1.00	2.96	2.96	2.96
diabetes mellitus	0.60	0.74	1.18	1.18	0.87	0.91	1.00	1.16
hypertension	1.20	2.12	3.59	5.85	1.20	1.44	1.72	2.07
liver disease	4.31	7.85	12.46	18.39	1.76	3.07	5.37	9.39
conduction disorders and other dysrhythmias	1.12	1.26	1.41	1.58	1.12	1.26	1.41	1.58
pancreatitis	1.06	1.27	1.72	2.62	1.06	1.27	1.72	2.62
ischaemic stroke 15-34	0.66	0.90	1.39	2.28	0.90	1.03	1.19	1.37
ischaemic stroke 35-64	0.68	0.91	1.36	2.16	0.90	1.03	1.18	1.34
ischaemic stroke 65+	0.76	0.93	1.25	1.75	0.93	1.02	1.13	1.24
ischaemic heart disease 15-34	0.87	1.00	1.00	1.00	0.80	0.79	0.95	1.00
ischaemic heart disease 35-64	0.88	1.00	1.00	1.00	0.81	0.81	0.96	1.00
ischaemic heart disease 65+	0.91	1.00	1.00	1.00	0.86	0.85	0.97	1.00

Remark:

- 1) ischaemic heart disease and stroke RR's were calculated for 3 different age groups
- 2) for ischaemic heart disease, RR is set to 1 if g/day is >60 g/day for men or >48 g/day for women or bingeing frequency is once a month or more
- 3) RR for injuries are not shown because AAF's for Mortality are derived from the Morbidity AAF and because the calculation also accounts for bingeing
- 4) RR for HIV are not shown because the calculation does not use a dose dependent relative risk function
